# Chapter 1

## An Introduction to the Theory of Representations of Groups

As I understand it, the fundamental idea behind Representation Theory is to study the actions of groups on vector spaces. While arbitrary vector spaces over arbitrary fields might not have naturally visualisable geometric properties, representations of groups in the ones that do can greatly illustrate the nature of these groups, especially to individuals like myself who delight in (somewhat literally) *seeing* mathematics come alive.

A key motivating example in the study of representation theory would be the representations of Dihedral groups over  $\mathbb{R}^2$ . It is very natural to (at least informally) view the Dihedral group  $D_n$  of order  $2n$  as the group of symmetries of the regular  $n$ -gon; in other words, elements of  $D_n$  have natural actions on a regular  $n$ -gon that preserve its structure. For instance,  $D_4$  contains an element that rotates a square clockwise by  $90^\circ$ , an action under which the square is, of course, invariant.

If one were to now plot this square in  $\mathbb{R}^2$ , then action of the same element on the square can be

extended to an orthogonal transformation of  $\mathbb{R}^2$  that maps the  $x$ -axis to the  $y$ -axis and vice-versa, but in a manner preserving orientation (ie, that *rotates the plane clockwise by  $90^\circ$* ). In a similar fashion, one can extend the actions of all dihedral groups  $D_n$  to actions on the entirety of  $\mathbb{R}^2$ . More precisely, to every element of a dihedral group, one can ascribe a specific *matrix* that transforms  $\mathbb{R}^2$  in a manner preserving the regular  $n$ -gon.

This motivates the formal definition of a representation.

## 1.1 Important Definitions

### 1.1.1 What is a Representation?

It turns out that representations can be defined quite broadly, sidestepping the geometric niceties (or are they constraints?) of Euclidean spaces.

**Definition 1.1.1** (Group Representation). Let  $G$  be a group. A representation of  $G$  is a pair  $(V, \rho)$  of a vector space  $V$  and a group homomorphism  $\rho : G \rightarrow \text{GL}(V)$ .

Here,  $\text{GL}(V)$  refers to the **General Linear** group over  $V$ , consisting of all vector space automorphisms of  $V$  equipped with the binary operation of composition.

**Definition 1.1.2** (Degree of a Representation). Let  $G$  be a group and let  $(V, \rho)$  be a representation of  $G$ . We define the degree of  $V$  to be the dimension of  $V$  over its base field.

There exist innumerable examples of representations throughout mathematics. Below, we give some important ones.

**Example 1.1.3** (Important Classes of Representations).

1. The trivial representation. Let  $G$  be a group and  $V$  be any vector space. The map  $\rho : G \rightarrow \text{GL}(V) : g \mapsto \text{id}_V$  is a representation.
2. The zero representation. Let  $G$  be a group and let  $V = \{0\}$  be the zero vector space over an arbitrary field  $K$ . The trivial representation over  $V$  is known as the zero representation.

3. The sign representation. Let  $G = S_n$ , the symmetric group on  $n$  elements, and let  $V = K$ , a field. Then,  $\text{GL}(V) = K^\times$ , the multiplicative group of  $K$ . Denoting by  $\xi$  the canonical morphism from  $\mathbb{Z}$  to  $K$ , the map

$$\rho : G \rightarrow \text{GL}(V) : \sigma \mapsto \xi(\text{sgn}(\sigma))$$

is a representation, where  $\text{sgn} : G \rightarrow \{-1, 1\}$  denotes the sign homomorphism.

4. Permutation representations. Let  $G$  be a group acting on a finite set  $X$ , and let  $V = K[X]$ , the free vector space (over some field  $K$ ) generated by  $X$ . Consider a  $K$ -basis  $\{e_x \in V : x \in X\}$  of  $V$ . Then, the map  $\rho : G \rightarrow \text{GL}(V)$  given by

$$\rho(g)(e_x) = e_{g(x)}$$

is a representation.

5. The regular representation. Let  $G$  be a *finite* group. The permutation representation corresponding to the canonical action of  $G$  on itself by left-multiplication gives a representation of  $G$  over  $K[G]$ , the free vector space generated by  $G$  (as a set) over any field  $K$ .

**Non-Example 1.1.4.** Let  $G$  be a group and let  $V$  be a nonzero vector space over an arbitrary field. The map  $g \mapsto 0 : G \rightarrow (V \rightarrow V)$  is not a representation because the zero map  $0 : V \rightarrow V$  is not invertible.

A useful perspective to adopt is that a representation is merely an action of a group on a vector space. And, just as faithful actions are an important class of actions, it will, later on, turn out to be important to have a corresponding notion for representations as well.

**Definition 1.1.5** (Faithfulness). Let  $G$  be a group and let  $(V, \rho)$  be a representation of  $G$ . We say  $(V, \rho)$  is faithful if  $\ker(\rho)$  is trivial.

In the next subsection, we begin to develop the theory of morphisms of representations, which will be crucial to the study of interactions and relationships between representations.

### 1.1.2 Morphisms of Representations

**Definition 1.1.6** (Homomorphism of Representations). Let  $G$  be a group and let  $(V, \rho)$  and  $(V', \rho')$  be two representations of  $G$ . A homomorphism of representations  $T : V \rightarrow V'$  is a linear map  $T : V \rightarrow V'$  such that  $\forall g \in G$ ,

$$T \circ \rho(g) = \rho'(g) \circ T$$

or equivalently, the following diagram commutes:

$$\begin{array}{ccc} V & \xrightarrow{\rho(g)} & V \\ T \downarrow & & \downarrow T \\ V' & \xrightarrow{\rho'(g)} & V' \end{array} \quad (1.1.1)$$

Such a map  $T$  is said to be  $G$ -linear.

*Remark.* The term  $G$ -linear comes from the fact that a homomorphism of representations satisfies the property that  $T(g(v)) = g(T(v))$ , where the notation  $g(\cdot)$  represents the action of some  $g \in G$ , encoded by a representation. In this sense,  $T$  is somehow “linear over  $G$ ”.

A natural way to define two representations to be equal, or ‘isomorphic,’ is as follows.

**Definition 1.1.7** (Equivalence of Representations). Let  $G$  be a group and let  $(V, \rho)$  and  $(V', \rho')$  be two representations of  $G$ . We say that  $(V, \rho)$  and  $(V', \rho')$  are equivalent, denoted  $(V, \rho) \sim (V', \rho')$ , if there exists a homomorphism  $T : (V, \rho) \rightarrow (V', \rho')$  that is invertible as a linear map—ie, that gives a linear isomorphism between  $V$  and  $V'$ .

Representations of the same group over the same vector space need not be equivalent.

**Example 1.1.8** (Non-Equivalent Representations of the Klein 4-Group). Let  $G = C_2 \times C_2$  be the Klein 4-group (where  $C_2 = \langle x \rangle$  is the cyclic group of order 2). Let  $\alpha = (x, 1)$  and  $\beta = (1, x)$ . Together, they generate  $G$ .

Now, let  $K$  be a field. Consider a degree 1 representation  $\rho : G \rightarrow K^\times$ . We know that  $\rho(G)$  must be a subgroup of  $K^\times$  such that  $|\rho(G)| \in \{1, 2, 4\}$ . If  $\text{char}(K) = 2$ , then  $\rho$  must be

the trivial representation, since  $2 \nmid |K^\times|$ . Else, all four maps  $\rho$  satisfying

$$(\rho(\alpha), \rho(\beta)) = (\pm 1, \pm 1)$$

give *non-equivalent* representations of  $G$  in  $K^\times$ . In particular, we see the non-equivalence because  $K^\times$  is commutative.

The point of morphisms of representations is to be able to move from one vector space to another without losing the structural information captured by the representation. This is precisely illustrated in (1.1.1).

**Example 1.1.9** (Representations of Cyclic Groups over  $\mathbb{R}^2$  and  $\mathbb{R}^3$ ). Consider the cyclic group  $C_n = \langle g \rangle$  of order  $n$ . Let  $V = \mathbb{R}^2, V' = \mathbb{R}^3$ . Together with the respective maps

$$\begin{aligned} \rho : G \rightarrow \text{GL}(\mathbb{R}^2) : g^m &\mapsto \begin{bmatrix} \cos(2\pi/m) & -\sin(2\pi/m) \\ \sin(2\pi/m) & \cos(2\pi/m) \end{bmatrix} \\ \rho' : G \rightarrow \text{GL}(\mathbb{R}^3) : g^m &\mapsto \begin{bmatrix} \cos(2\pi/m) & -\sin(2\pi/m) & 0 \\ \sin(2\pi/m) & \cos(2\pi/m) & 0 \\ 0 & 0 & 1 \end{bmatrix} \end{aligned}$$

they give representations of  $C_n$ . Consider now the inclusion  $T : \mathbb{R}^2 \rightarrow \mathbb{R}^3$  whose matrix with respect to the standard bases of  $\mathbb{R}^2$  and  $\mathbb{R}^3$  is  $\begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \end{bmatrix}$ . One can see that  $T$  gives a map from  $(V, \rho)$  to  $(V', \rho')$ . Indeed, the corestriction of  $T$  to its image is a linear isomorphism, which gives an equivalence between  $(V, \rho)$  and  $(T(V), \rho)$ , where we restrict the domains of each  $\rho(g^m)$  to  $T(V)$ .

The above example leads to an interesting question. Can we think of one representation as being “contained” in another?

It turns out that we can.

### 1.1.3 Subrepresentations

We have the objects; we have the morphisms. It is only natural to think about what the subobjects would be in the context of group representations. And if Example 1.1.9 is any indication, they involve something more than just an inclusion. There is some structural property of a sub-vector space of a representation that makes it *compatible* with the representation structure. In the case of Example 1.1.9, for instance, this is the fact that the representation  $\rho'$  acted only “horizontally”—ie, “parallel” to the subspace  $T(V)$ .

More generally, it turns out that the property we really require a subspace to have in order to be ‘compatible’ with the representation structure is the following.

**Definition 1.1.10** (*G*-Invariance). Let  $G$  be a group and let  $(V, \rho)$  be a representation of  $G$ . We say that a sub-vector space  $W \leq V$  is  $G$ -invariant if for all  $w \in W$  and  $g \in G$ ,

$$\rho(g)(w) \in W$$

In other words,  $W$  is  $G$ -invariant if  $W$  is  $\rho(g)$ -invariant for every  $g \in G$ .

One can make the following observation. Let  $G$  be a group,  $(V, \rho)$  a representation of  $G$ , and  $W \leq V$  a  $G$ -invariant subspace. Then,  $\forall g \in G$ ,  $\rho(g) \in \text{GL}(W)$ . That is,  $\rho(g)$  is a linear automorphism of  $W$  whose inverse,  $\rho(g^{-1})$ , is *also* a linear automorphism of  $W$ . This then leads to the following definition of a subrepresentation.

**Definition 1.1.11** (Subrepresentation). Let  $G$  be a group and let  $(V, \rho)$  be a representation of  $G$ . A subrepresentation of  $V$  is a pair  $(W, \rho|_W)$  consisting of a  $G$ -invariant subspace  $W \leq V$  and the map

$$\rho|_W : G \rightarrow \text{GL}(W) : g \mapsto \rho(g)|_W$$

It is very important to note that the map  $\rho|_W$  is *not actually a restriction of  $\rho$  to a specific domain*. Rather, it is a map that restricts the domain of  $\rho(g)$  for every  $g \in G$ .

One can also observe easily that a subrepresentation is given uniquely by a  $G$ -invariant subspace. Hence, we will often abuse notation and not distinguish between the pair  $(W, \rho|_W)$  (which is actually

a representation) and simply  $W$  (which is merely a subspace).

**Example 1.1.12.** Let  $G$  be a finite group and  $K$  a field. Consider the regular representation  $\rho : G \rightarrow K[G]$ . Let  $\{e_g : g \in G\}$  denote a basis of  $K[G]$ . Then, the subspace  $W := \text{Span}\left(\sum_{g \in G} e_g\right)$  is  $G$ -invariant.

It turns out that morphisms of representations also give us subrepresentations.

**Proposition 1.1.13.** *Let  $G$  be a group and let  $(V, \rho)$  be a representation of  $G$ . Let  $T : (V, \rho) \rightarrow (V, \rho)$  be a homomorphism of representations. Then, the subspaces  $\ker(T)$  and  $\text{im}(T)$  of  $V$  are  $G$ -invariant.*

*Proof.* Fix  $g \in G$  and  $v \in \ker(T)$ . We know  $T(\rho(g)(v)) = \rho(g)(T(v))$ . Since  $T(v) = 0$ ,  $T(\rho(g)(v)) = 0$ . Hence,  $\rho(g)(v) \in \ker(T)$ , proving that  $\ker(T)$  is  $G$ -invariant.

Now, fix  $w \in \text{im}(T)$ . Then,  $w = T(u)$  for some  $u \in V$ . Clearly,  $\rho(g)(w) = \rho(g)(T(u)) = T(\rho(g)(u)) \in \text{im}(T)$ , proving that  $\text{im}(T)$  is  $G$ -invariant as well.  $\square$

### 1.1.4 Irreducibility

Having discussed the subobjects of representations (namely, subrepresentation), it is only natural to wish to describe whether a representation ever contains a nontrivial subrepresentation. I say "nontrivial" because any representation naturally admits two (uninteresting) subrepresentations: the trivial representation and itself.

Akin to the definition of simple groups, where we answer a similar question, we have the following definition that captures this idea.

**Definition 1.1.14** (Irreducibility). Let  $G$  be a group and  $(V, \rho)$  a nonzero representation of  $G$ . We say  $(V, \rho)$  is irreducible if  $V$  contains no proper, nonzero  $G$ -invariant subspaces.

In similar fashion, we say a nonzero representation is reducible if it is not irreducible.

Given that MATH-314 focuses on *finite* groups, the following result is quite useful.

**Proposition 1.1.15.** *Let  $G$  be a group and let  $(V, \rho)$  be a representation of  $G$ . If  $G$  is finite and  $(V, \rho)$  is irreducible, then  $V$  is finite-dimensional.*

*Proof.* Since  $(V, \rho)$  is irreducible, in particular,  $V \not\supseteq \{0\}$ —ie,  $\exists v \in V$  such that  $v \neq 0$ . Let  $W := \text{Span}(\{\rho(g)(v) : g \in G\})$ . Since  $0 \neq v \in W$ ,  $W$  is a nonzero subspace of  $V$ . Furthermore, since  $G$  is finite,  $W$  is finite-dimensional. We show that  $W$  is, in fact,  $G$ -invariant. Then, since  $V$  is irreducible,  $W$  could not possibly be a proper subspace of  $V$ , meaning that  $W = V$ , making  $V$  finite-dimensional as well.

Fix  $h \in G$ , and consider an arbitrary element  $w = \sum_{g \in G} \lambda_g \rho(g)(v) \in W$ . Then,

$$\begin{aligned} \rho(h)(w) &= \sum_{g \in G} \lambda_g \rho(h)(\rho(g)(v)) \\ &= \sum_{g \in G} \lambda_g (\rho(h) \circ \rho(g))(v) \\ &= \sum_{g \in G} \lambda_g \rho(hg)(v) \in W \end{aligned}$$

proving that  $W$  is  $\rho(h)$ -invariant for every  $h \in G$ , making it a  $G$ -invariant subspace of  $V$ . Therefore, as argued above,  $W = V$ , proving that  $V$  is finite-dimensional.  $\square$

**Example 1.1.16** (Simple Examples of Irreducible Representations).

1. Any representation of degree 1 is irreducible.

*Proof.* A vector space of dimension 1 has no proper, nonzero subspaces— $G$ -invariant or otherwise. Hence, a representation of degree 1 *must* be irreducible  $\square$

2. Let  $K$  be a field. The trivial embedding  $\text{SL}(n, K) \hookrightarrow \text{GL}(n, K)$  gives an irreducible representation of  $\text{SL}(n, K)$  over  $K^n$ .

*Proof.* Assume  $n > 1$  (else, the result follows from the previous point). For the sake of contradiction, suppose there exists a nonzero,  $\text{SL}(n, K)$ -invariant subspace  $W$  of  $K^n$  having dimension  $m < n$ . Let  $\mathcal{B} = \{e_1, \dots, e_m\}$  be a basis of  $W$ , extending to a basis  $\overline{\mathcal{B}} = \{e_1, \dots, e_m, e_{m+1}, \dots, e_n\}$  of  $V$ . Consider the linear map  $T \in \text{SL}(n, K)$

having matrix

$$[T]_{\bar{B}} = \begin{bmatrix} & & & (-1)^{n+1} \\ & & \ddots & \\ & & -1 & \\ 1 & & & \end{bmatrix}$$

with respect to  $\bar{B}$ . Clearly,  $T(e_1) = e_n$ , even though  $e_1 \in W$  and  $e_n \notin W$ , contradicting the  $\mathrm{SL}(n, K)$ -invariance of  $W$ .  $\square$

**Non-Example 1.1.17.** Let  $G$  be a finite group and  $K$  a field. Consider the regular representation  $(K[G], \rho)$ . In the notation of Example 1.1.12, we know that  $W := \mathrm{Span}\left(\sum_{g \in G} e_g\right)$  is  $G$ -invariant. If  $|G| > 1$ , then  $W$  is a proper subspace of  $K[G]$ , as it has dimension 1 (whereas  $K[G]$  has dimension  $|G|$ ). Furthermore,  $W$  is nonzero. Hence,  $(K[G], \rho)$  is not irreducible (unless  $|G| = 1$ , in which case it follows from the first point of Example 1.1.16 that  $(K[G], \rho)$  is irreducible).

We also have the following interesting criterion for irreducibility of representations of finite groups over  $\mathbb{C}$ .

**Lemma 1.1.18.** *Let  $G$  be a finite group and let  $(\mathbb{C}^2, \rho)$  be a representation of  $G$  over  $\mathbb{C}$ . If there exist  $g, h \in G$  such that  $\rho(g)$  and  $\rho(h)$  do not commute, then  $(\mathbb{C}^2, \rho)$  is irreducible.*

*Proof.* We argue by contraposition. Suppose that  $(\mathbb{C}^2, \rho)$  is reducible. Let  $W \leq \mathbb{C}^2$  denote a proper, nonzero,  $G$ -invariant subspace. Clearly,  $\dim(W) = 1$ . This means that as a  $\mathbb{C}$ -vector space,  $W \cong \mathbb{C}$ . Indeed,  $\mathrm{GL}(W) \cong \mathbb{C}^\times$ . Seeing as  $\mathbb{C}^\times$  is abelian, there cannot possibly exist such a  $g$  and  $h$ . So, if they do exist, then  $(\mathbb{C}^2, \rho)$  must be irreducible.  $\square$

## 1.2 Invariant Constructions

In this section, we briefly examine how ordinary linear algebraic constructions can interact with representations. We are particularly interested in the notion of *invariance*, wherein a linear algebraic construction respects the structure of any representations involved.

### 1.2.1 Direct Sums of Representations

The most elementary operation we can think about when we have two objects is *putting them together*. One of the most meaningful ways of doing so in the context of linear algebra is the direct sum of two vector spaces. It turns out that this extends rather naturally to representations.

**Definition 1.2.1** (The Direct Sum of Two Representations). Let  $G$  be a group and let  $(V, \rho)$  and  $(V', \rho')$  be representations of  $G$ . We define the direct sum of  $(V, \rho)$  and  $(V', \rho')$  to be the pair  $(V \oplus V', \rho \oplus \rho')$ , where  $V \oplus V'$  is the direct sum of  $V$  and  $V'$  as vector spaces and  $\rho \oplus \rho' : G \rightarrow \text{GL}(V \oplus V')$  maps every  $g \in G$  to the map

$$(\rho \oplus \rho')(g)(v \oplus v') = \rho(g)(v) \oplus \rho'(g)(v') \in \text{GL}(V)$$

**Proposition 1.2.2.** Let  $G$  be a group and let  $(V, \rho)$  and  $(V', \rho')$  be representations of  $G$ .

1. The direct sum  $(V \oplus V', \rho \oplus \rho')$  of  $(V, \rho)$  and  $(V', \rho')$  is, indeed, a representation of  $G$ .
2.  $V$  and  $V'$  are  $G$ -invariant subspaces<sup>1</sup> of  $V \oplus V'$ .

*Proof.*

1. Fix  $g, h \in G$ . For all  $v \oplus v' \in V \oplus V'$ ,

$$\begin{aligned} (\rho \oplus \rho')(gh)(v \oplus v') &= \rho(gh)(v) \oplus \rho'(gh)(v') \\ &= \rho(g)(\rho(h)(v)) \oplus \rho'(g)(\rho'(h)(v')) \\ &= (\rho \oplus \rho')(g)((\rho \oplus \rho')(h)(v \oplus v')) \end{aligned}$$

proving that  $\rho \oplus \rho'$  is multiplicative. Then, for any  $g \in G$ ,  $(\rho \oplus \rho')(g)$  has inverse  $(\rho \oplus \rho')(g^{-1})$ .

Hence,  $\rho \oplus \rho'$  is a homomorphism from  $G$  to  $\text{GL}(V \oplus V')$ .

2. Fix  $g \in G$  and  $v \in V$ . Clearly,  $(\rho \oplus \rho')(g)(v) = \rho(g)(v)$ . Since  $\rho(g) \in \text{GL}(V)$ , it follows that  $\rho(g)(v) \in V$ . The proof that  $V'$  is  $G$ -invariant is identical.

□

The above proposition gives us another reason to consider the direct sum to be an “invariant”

<sup>1</sup>Technically, isomorphic to the subspaces  $V \oplus \{0\}$  and  $\{0\} \oplus V'$ , but we overlook such distinctions.

construction: while it enriches both the vector space structure and the representation structure of a summand by adding another representation into the mix, it does not take anything away from the constructions that already exist.

With direct sums, we also have similar notions to reducibility.

**Definition 1.2.3** (Indecomposability). A nonzero representation is said to be indecomposable if it is inexpressible as a direct sum of two proper, nonzero subrepresentations.

Nonzero representations that are not indecomposable are said to be decomposable.

We have a natural relationship between irreducibility and indecomposability.

**Proposition 1.2.4.** *Let  $G$  be a group and let  $(V, \rho)$  be a representation of  $G$ . If  $(V, \rho)$  is irreducible, then it is indecomposable.*

*Proof.* If  $V = \{0\}$ , then the result is vacuously true. If  $V \neq \{0\}$ , then if it is decomposable, it contains a proper, nonzero,  $G$ -invariant subspace, making it reducible.  $\square$

**Example 1.2.5.** Let  $C_2 = \{1, a\}$  be the cyclic group of order 2, and let  $(V, \rho)$  be the regular representation of  $C_2$  over a field  $K$ .

1. Let  $K = \mathbb{C}$ . Then, let  $W_1 := \text{Span}(e_1 + e_a)$  and  $W_2 := \text{Span}(e_1 - e_a)$ . It is obvious that  $W_1 \oplus W_2 = V$ , as vector spaces. Furthermore,  $W_1$  and  $W_2$  are both  $C_2$ -invariant. Hence,  $W_1 \oplus W_2 = V$  as representations, too. One would say that the regular representation of  $C_2$  over  $\mathbb{C}$  is decomposable.
2. Let  $K = \mathbb{F}_2$ . Then,  $V = \{0, e_1, e_a, e_1 + e_a\}$ . Observe that  $W := \{0, e_1 + e_a\}$  is a proper,  $C_2$ -invariant subspace of  $V$ . Hence,  $(V, \rho)$  is reducible. However,  $W$  is the *only* such subspace, meaning  $(V, \rho)$  cannot be expressed as a direct sum of *two* proper, nonzero subrepresentations. Therefore,  $(V, \rho)$  is indecomposable.

The  $K = \mathbb{F}_2$  case in the above example demonstrates an important fact: *the converse of Proposition 1.2.4 is not, in general, true.* It is natural to wonder if we can, at least, prove a *partial* converse. It turns out that we can: the converse is true under (indeed, equivalent to) a very specific condition.

While we do not yet have the tools we need to prove this result, it will be worth the wait, as it will turn out to be a direct consequence of a more powerful theorem proved by Heinrich Maschke (and the converse thereof).

Finally, just like in other areas of mathematics where we encounter the word “irreducible,” in the context of representation theory, too, we have a notion of decomposition into irreducibles.

**Definition 1.2.6** (Complete Reducibility). A representation is said to be completely reducible if it is expressible as a direct sum of irreducible representations.

Note that by this definition, any irreducible representation is completely reducible—it is a direct sum of only one irreducible representation, namely, itself.

Indecomposability and complete reducibility are intrinsically connected. The following proposition will eventually be part of a chain of equivalences that will establish a converse of Proposition 1.2.4 using Maschke’s Theorem and its converse.

**Proposition 1.2.7.** *Let  $G$  be a group and let  $(V, \rho)$  be a representation of  $G$ . Let  $K$  be a field. All indecomposable, finite-dimensional representations of  $G$  over  $K$  are irreducible if and only if every finite-dimensional representation of  $G$  over  $K$  is completely reducible.*

*Proof.*

(  $\implies$  ) Let  $(V, \rho)$  be a finite-dimensional representation of  $G$  over  $K$ . If  $(V, \rho)$  is indecomposable, it is irreducible, making it completely reducible. Else,  $(V, \rho)$  is decomposable, making it a direct sum of two proper, nonzero subrepresentations. We can construct an inductive argument (on  $\dim(V)$ ) to show that each of these subrepresentations is completely reducible. We can then conclude that  $(V, \rho)$  is completely reducible.

(  $\impliedby$  ) Let  $(V, \rho)$  be a finite-dimensional, indecomposable representation of  $G$  over  $K$ . By assumption,  $(V, \rho)$  is expressible as a direct sum of irreducible representations. Since  $(V, \rho)$  is indecomposable, none of the summands can be proper or nonzero. Therefore,  $(V, \rho)$  must be a direct sum of *one* irreducible representation—namely, itself.

□

It turns out that complete reducibility can be better understood through complementary subrepresentations.

## 1.2.2 Complementary Subrepresentations

It is a well-known fact from Linear Algebra that for any finite-dimensional vector space  $V$ , for any subspace  $W \leq V$ , there exists a *complementary* subspace  $W' \leq V$  such that  $W \oplus W' = V$ . As it turns out, we can define a notion of complementarity for representations, too.

**Definition 1.2.8** (Complementary Subrepresentation). Let  $G$  be a group and let  $(V, \rho)$  be a representation of  $G$ . Let  $(W, \rho|_W)$  be a subrepresentation of  $(V, \rho)$ . A complementary subrepresentation of  $(W, \rho|_W)$  is a subrepresentation  $(U, \rho|_U)$  such that  $V = U \oplus W$ .

This notion of complementarity is, indeed, compatible with the notion of direct sums of representations.

**Proposition 1.2.9.** *Let  $G$  be a group and let  $(V, \rho)$  be a representation of  $G$ . Let  $(W, \rho|_W)$  and  $(U, \rho|_U)$  be complementary subrepresentations. Then, their direct sum  $(V, \rho|_W \oplus \rho|_U)$  is equivalent to  $(V, \rho)$  as a representation of  $G$ .*

*Proof.* It suffices to show that  $\rho = \rho|_W \oplus \rho|_U$ . Then, the identity map would give an equivalence of representations. Indeed, every  $v \in V$  is expressible uniquely as a direct sum  $w \oplus u$  for some  $w \in W$  and  $u \in U$ . So, for all  $g \in G$ ,

$$\begin{aligned} \rho(g)(v) &= \rho(g)(w \oplus u) \\ &= \rho(g)(w) \oplus \rho(g)(u) \\ &= \rho|_W(g)(w) \oplus \rho|_U(g)(u) \\ &= (\rho|_W \oplus \rho|_U)(g)(w \oplus u) \end{aligned}$$

where the sum in the second equality is direct because  $W$  and  $U$  are  $\rho(g)$ -invariant. □

We now recall an important result from Linear Algebra.

**Definition 1.2.10** (Projection). Let  $V$  be a vector space and let  $T : V \rightarrow V$  be linear. Observe that we have the following equivalence:

$$T^2 = T \iff \forall w \in \text{im}(T), T(w) = w \quad (1.2.1)$$

If  $T$  satisfies either one of the above conditions,  $T$  is said to be a projection.

We do not prove (1.2.1), but we do prove the following lemma, which will prove to be useful.

**Lemma 1.2.11.** *Let  $V$  be a vector space. For all projections  $T : V \rightarrow V$ ,  $V = \ker(T) \oplus \text{im}(T)$ .*

*Proof.* Let  $T : V \rightarrow V$  be a projection. We then have the following.

$\text{im}(T) \cap \ker(T) = \{0\}$ : Fix  $w \in \text{im}(T) \cap \ker(T)$ . Since  $w \in \text{im}(T)$ ,  $\exists v \in V$  such that  $w = T(v)$ .

Furthermore, since  $w \in \ker(T)$ ,  $T(w) = 0$ . Since  $w = T(v)$ , this is equivalent to saying that  $T(T(v)) = 0$ . But, by (1.2.1),  $T(T(v)) = T(v)$ . Hence,  $T(v) = 0$ . Then, since  $T(v) = w$ , it follows that  $w = 0$ .

$V = \ker(T) + \text{im}(T)$ : Fix  $v \in V$ . We write  $v = T(v) + (v - T(v))$ . Clearly,  $T(v) \in \text{im}(T)$ .

Further,  $T(v - T(v)) = T(v) - T(v) = 0$ . Hence,  $v - T(v) \in \ker(T)$ .

Therefore, we do, indeed, have  $V = \ker(T) \oplus \text{im}(T)$ . □

It turns out that this gives us an important criterion for decomposability.

**Corollary 1.2.12.** *Let  $G$  be a group and let  $(V, \rho)$  be a representation of  $G$ . If  $T : (V, \rho) \rightarrow (V, \rho)$  is a  $G$ -linear projection, then  $V = \ker(T) \oplus \text{im}(T)$  is a direct sum of subrepresentations.*

*Proof.* The result follows immediately from Lemma 1.2.11 and Proposition 1.1.13. □

One also has a converse criterion for  $G$ -linearity.

**Proposition 1.2.13.** *Let  $G$  be a group and let  $(V, \rho)$  be a representation of  $G$ , and let  $T : V \rightarrow V$  be a projection. If  $\ker(T)$  and  $\text{im}(T)$  are both  $G$ -invariant, then  $T$  is  $G$ -linear.*

*Proof.* Since  $T$  is a projection, we know that  $V = \ker(T) \oplus \text{im}(T)$ . Now, fix  $g \in G$  and  $v \in V$ .

We know  $v$  can uniquely be expressed as  $u + w$ , where  $u \in \ker(T)$  and  $w \in \operatorname{im}(T)$ . Then,

$$\begin{aligned} T(\rho(g)(v)) &= T\left(\underbrace{\rho(g)(u)}_{\in \ker(T)} + \underbrace{\rho(g)(w)}_{\in \operatorname{im}(T)}\right) \\ &= \rho(g)(w) \\ &= \rho(g)(T(v)) \end{aligned}$$

proving that  $T$  is, indeed,  $G$ -linear. □

**Example 1.2.14.** Consider the situation in Example 1.1.9. As we discussed briefly at the beginning of Subsection 1.1.3, we can view  $(V, \rho)$  as a subrepresentation of  $(V', \rho')$ . Now, consider the linear map  $S : V' \rightarrow V' : (x, y, z) \mapsto (x, y, 0)$ , where  $(x, y, z)$  are coordinates with respect to the standard basis. This is clearly a projection operator with image  $V$ , the  $(x, y)$  plane, and kernel the  $z$ -axis. These are both clearly  $G$ -invariant, making  $S$  a  $G$ -linear projection.

Finally, we relate complementary subrepresentations and complete reducibility, which makes it clear why we are so interested in complementary subrepresentations.

**Proposition 1.2.15.** *A finite-dimensional representation of a finite group is completely reducible if and only if each of its subrepresentations admits a complementary subrepresentation.*

*Proof.* Let  $G$  be a finite group and let  $(V, \rho)$  be a finite-dimensional representation of  $G$ .

( $\implies$ ) Assume  $(V, \rho)$  is completely reducible, with decomposition  $V = \bigoplus_{i \in \mathcal{I}} W_i$  into irreducible subrepresentations. Let  $U \leq V$  be  $G$ -invariant.

( $\impliedby$ ) Assume every subrepresentation of  $(V, \rho)$  admits a complementary subrepresentation. We know that  $(V, \rho)$  is either irreducible, in which case we'd be done, or reducible, in which case there exists a proper, nonzero,  $G$ -invariant subspace  $W \leq V$ . We know that  $W$  admits a complementary subrepresentation  $U \leq V$ , which must also be proper and nonzero. We can argue by induction on the dimension to completely reduce both  $W$  and  $U$  (ie, express them as direct sums of irreducibles). We can then conclude that  $(V, \rho)$  is completely reducible.

□

### 1.2.3 Maschke's Theorem

Given the theme of this section—namely, understanding the compatibility of ordinary linear-algebraic constructions with representation structures—one might wonder under what conditions (if any) we have the existence of a complementary subrepresentations. The answer lies in Maschke's Theorem, which is the first major result of the course.

**Theorem 1.2.16** (Maschke's Theorem). *Let  $G$  be a finite group,  $K$  a field such that  $\text{char}(K) \nmid |G|$ , and  $(V, \rho)$  a representation of  $G$  over  $K$ . Then, any subrepresentation of  $V$  admits a complementary subrepresentation.*

*Proof.* Let  $W \leq V$  be  $G$ -invariant. The idea is to construct a  $G$ -linear map from  $V$  to  $V$  with image  $W$ . Then, by Corollary 1.2.12, its kernel would give a complementary subrepresentation.

From Linear Algebra, we know that  $W$  admits a complementary (but not necessarily  $G$ -invariant) subspace  $U \leq V$ . Then, every  $v \in V$  can uniquely be expressed as a sum  $u + w$ , where  $u \in U$  and  $w \in W$ . Define  $T : V \rightarrow V : u + w \mapsto w$ . Clearly,  $T$  is a projection operator with image  $W$  and kernel  $U$ .

If  $T$  were  $G$ -linear, we would be done with the proof; unfortunately,  $T$  does not have to be  $G$ -linear. We therefore “convert”  $T$  into a  $G$ -linear projection  $S : V \rightarrow V$  by *averaging over  $G$* . Specifically, define

$$S := \frac{1}{|G|} \sum_{g \in G} \rho(g) \circ T \circ \rho(g)^{-1} \quad (1.2.2)$$

which is well-defined because  $|G| \neq 0$  in  $K$ . We then show the following.

$S$  is a projection with image  $W$ . Fix  $v \in V$  and express it as  $u + w$  for a unique  $u \in U$  and  $w \in W$ . Then, for all  $g \in G$ ,

- $T(\rho(g)^{-1}(v)) \in W$  because  $T$  is a projection with image  $W$ .
- $\rho(g)(T(\rho(g)^{-1}(v))) \in W$  because  $T(\rho(g)^{-1}(v)) \in W$  and  $W$  is  $G$ -invariant.

Combined with the fact that  $W$  is closed under addition, this proves that  $\text{im}(S) \subseteq W$ . Conversely, for all  $w \in W$  and  $g \in G$ ,

- $(\rho(g)^{-1})(w) = \rho(g^{-1})(w) \in W$  because  $W$  is  $G$ -invariant.
- $T(\rho(g^{-1})(w)) \in W$  because  $\rho(g^{-1})(w) \in W$  and  $W$  is  $T$ -invariant.
- $\rho(g)(T(\rho(g^{-1})(w))) \in W$  because  $W$  is  $G$ -invariant.

Combined, again, with the fact that  $W$  is closed under addition, this proves that  $W \subseteq \text{im}(S)$ . Therefore, we have that  $W = \text{im}(S)$ .

Finally, since  $T|_W = \text{id}_W$ , we have that  $\forall w \in \text{im}(S) = W$ ,

$$\begin{aligned} S(w) &= \frac{1}{|G|} \sum_{g \in G} \rho(g) \left( T \left( \underbrace{\rho(g)^{-1}(w)}_{\in W} \right) \right) \\ &= \frac{1}{|G|} \sum_{g \in G} (\rho(g) \circ \rho(g)^{-1})(w) \\ &= \frac{1}{|G|} \sum_{g \in G} w = w \end{aligned}$$

proving that  $S$  is, indeed, a projection.

$S$  is  $G$ -linear. Fix  $v \in V$  and  $h \in G$ . We have

$$\begin{aligned} S(\rho(h)(v)) &= \frac{1}{|G|} \sum_{g \in G} (\rho(g) \circ T \circ \rho(g)^{-1})(\rho(h)(v)) \\ &= \frac{1}{|G|} \sum_{g \in G} (\rho(g) \circ T \circ \rho(g^{-1}h))(v) \end{aligned}$$

We now perform a change of variables. Observe that the map  $g \mapsto h^{-1}g : G \rightarrow G$  is an automorphism. Hence, writing  $g' = h^{-1}g$ , we have

$$\begin{aligned} S(\rho(h)(v)) &= \frac{1}{|G|} \sum_{g' \in G} (\rho(hg') \circ T \circ \rho((g')^{-1}))(v) \\ &= \rho(h) \left( \frac{1}{|G|} \sum_{g' \in G} (\rho(g') \circ T \circ \rho(g')^{-1}) \right) (v) \\ &= \rho(h)(S(v)) \end{aligned}$$

proving that  $S$  is, indeed,  $G$ -linear.

Therefore, by Corollary 1.2.12,  $\ker(S)$  is a complementary subrepresentation of  $W$ .  $\square$

We also have the following important corollary.

**Corollary 1.2.17.** *Let  $G$  be a finite group,  $K$  a field such that  $\text{char}(K) \nmid |G|$ . Then, every representation of  $G$  over  $K$  is completely reducible.*

*Proof.* Let  $(V, \rho)$  be a representation of  $G$  over  $K$ . If  $(V, \rho)$  is irreducible, we are done; else, it admits a nonzero, proper subrepresentation, which, by Maschke's Theorem, admits a complementary subrepresentation that is also proper and nonzero. If both of these are irreducible, then we are done; else, repeat this process.  $\square$

*Remark.* Nowhere in Definition 1.2.6 do we specify that the decomposition must be finite.

We note that both hypotheses of Maschke's Theorem—namely, that  $G$  is a finite group and that  $\text{char}(K) \nmid |G|$ —are essential for Theorem 1.2.16 (and hence Corollary 1.2.17) to hold.

**Non-Example 1.2.18** (Failure of Maschke's Theorem when  $\text{char}(K) \mid |G|$ ). Let  $G = \langle a \rangle$  be a cyclic group of prime order  $p$ . Let  $V = \mathbb{F}_p^2$ , and define  $\rho : G \rightarrow \text{GL}(2, \mathbb{F}_p)$  by

$$\rho(a^r) = \begin{bmatrix} 1 & r \\ 0 & 1 \end{bmatrix} \quad \text{for } 0 \leq r \leq p-1.$$

1.  $(V, \rho)$  is a representation of  $G$  over  $\mathbb{F}_p$ .
2.  $(V, \rho)$  is not irreducible.
3.  $(V, \rho)$  is not completely reducible.

It turns out that Maschke's Theorem also has a *converse*.

**Theorem 1.2.19** (Converse of Maschke's Theorem). *Let  $G$  be a finite group such that every finite-dimensional representation of  $G$  over some field  $K$  is completely reducible. Then,  $\text{char}(K) \nmid |G|$ .*

*Proof.* Consider the regular representation  $(K[G], \rho)$  of  $G$  over  $K$ , with basis  $\mathcal{B} = \{e_g : g \in G\}$ . The idea is to take advantage of the  $G$ -invariant properties of  $\mathcal{B}$ .

Consider the subspace

$$W := \left\{ \sum_{g \in G} \alpha_g e_g : \sum_{g \in G} \alpha_g = 0 \right\}$$

of dimension  $\dim(V) - 1$ . It turns out that  $W$  is  $G$ -invariant: for all  $\sum_{g \in G} \alpha_g e_g \in W$  and  $h \in G$ , we have

$$\rho(h) \left( \sum_{g \in G} \alpha_g e_g \right) = \sum_{g \in G} \alpha_g e_{hg} \in W$$

(where the sum of the coefficients  $\alpha_g$  is still zero). Then, by assumption,  $\exists U \leq V$  that is both  $G$ -invariant and complementary to  $W$ . This means that  $U$  must be of dimension 1, and is hence the span of a single vector  $u \in U$ .

We study the action of  $G$  on  $U$ . Fix  $h \in G$ , and write  $u = \sum_{g \in G} \beta_g e_g$  for  $\beta_g \in K$ . Then,

$$\rho(h)(u) - u = \sum_{g \in G} \underbrace{\beta_g e_{hg} - \beta_g e_g}_{\in W}$$

meaning that  $\rho(h)(u) - u \in W$ . But,  $\rho(h)(u) - u \in U$  as well. Since  $U \cap W = \{0\}$ , this means that  $\rho(h)(u) = u$  for all  $h \in G$ . Hence, the action of  $G$  on  $U$  is *trivial*. Therefore, for all  $x \in G$ ,

$$\sum_{g \in G} \beta_g e_{hg} = \sum_{g \in G} \beta_g e_g$$

Comparing coefficients, we conclude that  $\beta_{h^{-1}g} = \beta_g$  for all  $h, g \in G$ . Letting  $h = g$ , we get, in particular, that  $\forall g \in G, \beta_g = \beta_1$ . Therefore,  $u = \beta_1 \sum_{g \in G} e_g$ . This, in particular, implies that  $u' := \sum_{g \in G} e_g \notin W$ , because otherwise,  $u = \beta_1 u'$  would also lie in  $W$ , which it does not. Therefore, the sum of the coordinates of  $u'$  with respect to  $\mathcal{B}$  cannot be zero. But, this sum is nothing but the cardinality of  $G$  (or rather, its image in the canonical map  $\mathbb{Z} \rightarrow K$ ). Since this is nonzero, it must be that  $\text{char}(K) \nmid |G|$ , as required.  $\square$

Combining Theorems 1.2.16 and 1.2.19 gives us the promised partial converse of Proposition 1.2.4:

**Corollary 1.2.20.** *Let  $G$  be a finite group and let  $K$  be a field. All indecomposable representations of  $G$  are irreducible if and only if  $\text{char}(K)$  does not divide  $|G|$ .*

*Proof.*

$\square$

### 1.2.4 $G$ -Invariant Inner-Products

It turns out that we also have a notion of inner-products being compatible with representation structures.

**Definition 1.2.21** ( $G$ -Invariant Inner-Product). Let  $G$  be a group and let  $(V, \rho)$  be a representation of  $G$  over  $\mathbb{C}$  such that  $V$  admits an inner-product  $\langle \cdot, \cdot \rangle$ . We say that  $\langle \cdot, \cdot \rangle$  is  $G$ -invariant if  $\forall g \in G$  and  $\forall x, y \in V$ ,

$$\langle x, y \rangle = \langle \rho(g)(x), \rho(g)(y) \rangle$$

Equivalently,  $\langle \cdot, \cdot \rangle$  is  $G$ -invariant if  $\text{im}(\rho) \subseteq U(V)$ , ie, if, for every  $g \in G$ ,  $\rho(g)$  is a *unitary*  $\mathbb{C}$ -linear map from  $V$  to  $V$ .

Intrinsic to the notion of an inner-product is that of orthogonality. In the following proposition, we understand the significance of  $G$ -invariance in the context of subrepresentations.

**Proposition 1.2.22.** *Let  $G$  be a group and let  $(V, \rho)$  be a representation of  $G$  over  $\mathbb{C}$  of finite dimension. Let  $\langle \cdot, \cdot \rangle$  be a  $G$ -invariant inner-product on  $V$ . Then, the orthogonal complement of any  $G$ -invariant subspace of  $V$  is also  $G$ -invariant.*

*Proof.* Let  $W \leq V$  be  $G$ -invariant, and denote by  $W^\perp$  its orthogonal complement. Fix  $g \in G$  and  $w \in W^\perp$ . To show that  $\rho(g)(w) \in W^\perp$ , we show it is orthogonal to every  $v \in W$  with respect to  $\langle \cdot, \cdot \rangle$ .

Fix  $v \in W$ . Then, since  $\langle \cdot, \cdot \rangle$  is  $G$ -invariant,

$$\begin{aligned} \langle v, \rho(g)(w) \rangle &= \langle \rho(g^{-1})(v), \rho(g^{-1}g)(w) \rangle \\ &= \langle \rho(g^{-1})(v), w \rangle \end{aligned}$$

Since  $W$  is  $G$ -invariant,  $\rho(g^{-1})(v) \in W$ , making it orthogonal to  $w$ , which lies in the orthogonal complement of  $W$ . Therefore,  $\langle v, \rho(g)(w) \rangle = 0$ , proving that  $\rho(g)(w) \in W^\perp$  as required.  $\square$

**Corollary 1.2.23.** *Let  $G$  be a group and let  $(V, \rho)$  be a representation of  $G$  over  $\mathbb{C}$ . If  $V$  is finite dimensional and admits a  $G$ -invariant inner-product, then  $V$  is completely reducible.*

*Proof.* If  $V$  is finite dimensional and admits a  $G$ -invariant inner-product, then by Proposition 1.2.22, for any  $W \leq V$   $G$ -invariant,  $W^\perp$  is  $G$ -invariant as well. Since  $W \oplus W^\perp = V$  and both  $W$  and  $W^\perp$  are finite-dimensional, we can prove the result using similar reasoning to what we used to prove Corollary 1.2.17.  $\square$

## 1.2.5 Tensor Products of Representations

We begin by recalling the notion of a tensor product of two finite-dimensional vector spaces.

**Definition 1.2.24** (Tensor Product of Vector Spaces). Let  $K$  be a field and let  $V, W$  be finite-dimensional vector spaces over  $K$  with bases  $\{v_i\}$  and  $\{w_j\}$  respectively. The tensor product of  $V$  and  $W$ , denoted  $V \otimes_K W$ , is a vector space of dimension  $\dim(V)\dim(W)$  with basis

$$\{v_i \otimes w_j : 1 \leq i \leq \dim(V), 1 \leq j \leq \dim(W)\} \quad (1.2.3)$$

such that the map

$$\otimes_K : V \times W \rightarrow V \otimes_K W : (v, w) \mapsto v \otimes_K w$$

is bilinear.

*Remark.* Sometimes, when the base field (or ring) is clear from the context, we omit the subscript in the notation for the tensor product.

In similar fashion to Definition 1.2.1, we can extend this definition to representations.

**Definition 1.2.25** (Tensor Product of Representations). Let  $G$  be a finite group and let  $(V, \rho)$  and  $(W, \rho')$  be representations of  $G$  over  $K$ . The tensor product of  $(V, \rho)$  and  $(V', \rho')$ , denoted  $(V, \rho) \otimes (V', \rho')$ , is a representation of  $G$  over  $K$  with underlying set  $V \times_K V'$  and action

$$(\rho \otimes_K \rho')(g)(v \otimes_K v') = \rho(g)(v) \otimes_K \rho'(g)(v') \in \text{GL}(V)$$

We will see more of the properties of Tensor Products as we go along, primarily in Section 3.3. We do not go into more detail here as the multiplicative properties of the tensor product are best appreciated if considered alongside a well-developed theory of characters. Until then, the invariant

construction whose properties we will explore in detail shall be the direct sum.

## 1.3 Group Algebras and Modules

In this section, we study an important class of field algebras, namely, group algebras, and an important class of modules over said algebras, namely, group modules.

### 1.3.1 Preliminaries

**Definition 1.3.1** (Group Algebra). Let  $G$  be a finite group and let  $K$  be a field. The group algebra  $KG$  is the  $K$ -algebra obtained by endowing the free vector space  $K[G]$  generated by  $G$  (as a set) with the multiplication

$$\left( \sum_{g \in G} \alpha_g e_g \right) \cdot \left( \sum_{g \in G} \beta_g e_g \right) := \sum_{g \in G} \sum_{h \in G} \alpha_g \beta_h e_{gh}$$

*Remark.*

1. It is easy to verify that  $KG$  is, indeed, a  $K$ -algebra, with the multiplicative identity given by  $e_1$  (where  $1 \in G$  is the identity).
2. The map  $g \mapsto e_g : G \rightarrow KG$  gives a trivial embedding of  $G$  in  $KG$ .
3. Going forward, for ease of notation, we will denote each basis element  $e_g$  as simply  $g$ .

We have a similar notion of group modules.

**Definition 1.3.2** (Group Module). Let  $G$  be a group and let  $V$  be a vector space over a field  $K$ . We say that  $V$  is a  $KG$ -module if we can define a multiplication  $g \cdot v$  for some  $g \in G$  and  $v \in V$  that satisfies the following conditions for all  $u, v \in V$ ,  $g, h \in G$  and  $\lambda \in K$ :

1.  $g \cdot v \in V$
2.  $(gh) \cdot v = g \cdot (h \cdot v)$
3.  $1 \cdot v = v$
4.  $g \cdot (\lambda v) = \lambda(g \cdot v)$

$$5. \quad g \cdot (u + v) = g \cdot u + g \cdot v$$

Note that a  $KG$ -module is, indeed, a module over  $KG$ .

**Proposition 1.3.3.** *Let  $G$  be a group and let  $V$  be a vector space over a field  $K$ . If  $V$  is a  $KG$ -module with multiplication  $\cdot$  (as per Definition 1.3.2), then for  $v \in V$ , the multiplication*

$$\left( \sum_{g \in G} \lambda_g e_g \right) \cdot v := \sum_{g \in G} \lambda_g (g \cdot v)$$

*endows  $V$  with a module structure over  $K[G]$ .*

Furthermore, it turns out that we can move from modules to representations and vice-versa quite easily.

**Proposition 1.3.4.** *Let  $G$  be a group and let  $V$  be a vector space over a field  $K$ .*

1. *If  $\rho : G \rightarrow \text{GL}(V)$  gives a representation of  $G$ , then  $V$  is a  $KG$ -module with multiplication given by  $g \cdot v = \rho(g)(v)$  for all  $g \in G$  and  $v \in V$ .*
2. *If  $V$  is a  $KG$ -module with multiplication  $\cdot$ , the map  $\rho : G \rightarrow \text{GL}(V)$  given by  $\rho(g)(v) := g \cdot v$  is a representation.*

The proofs of the above propositions are trivial and merely involve manually checking several basic conditions. Hence, we omit them.

We now give a basic ‘dictionary’ of sorts to go back and forth between the language of group modules and that of representations:

<b><math>KG</math>-Modules</b>	<b>Representations</b>
Simple	Irreducible
Semi-Simple	Completely Irreducible
Submodule	Subrepresentation
Viewing $KG$ as a $KG$ -Module	The Regular Representation
Isomorphism	Equivalence of Representations
Dimension (as a $K$ -vector space)	Degree

We illustrate the above equivalence by stating Maschke’s Theorem in the language of  $KG$ -Modules.

**Lemma 1.3.5** (Maschke's Theorem, Module Version). *Let  $G$  be a finite group,  $K$  a field whose characteristic does not divide the order of  $G$ . Then, any  $KG$ -Module  $V$  is semi-simple.*

### 1.3.2 Schur's Lemmas

In this subsection, we explore several versions of an important result by Schur. The main result consists of two cases, the first of which shall (by convention) deal with the non-isomorphic case and the second of which shall deal with the isomorphic case. We will refer to them as Schur's First and Second Lemmas respectively. We begin by stating them in their most general form.

**Theorem 1.3.6** (Schur's Lemmas for Rings). *Let  $A$  be a ring and let  $S, T$  be simple  $A$ -modules.*

1. *If  $S$  and  $T$  are non-isomorphic, then  $\text{Hom}_A(S, T) = \{0\}$ .*
2. *If  $S$  and  $T$  are isomorphic, then  $\text{Hom}_A(S, T)$  is a division ring.*

*Proof.* We rely on the fact that for all  $\phi \in \text{Hom}_A(S, T)$ ,  $\ker(\phi) \leq S$  and  $\text{im}(\phi) \leq T$ .

1. Let  $S$  and  $T$  be non-isomorphic. Fix  $\phi \in \text{Hom}_A(S, T)$ . Since  $S$  is simple, we must have that  $\ker(\phi) \in \{\{0\}, S\}$ . If  $\ker(\phi) = \{0\}$ , then  $\text{im}(\phi) = T$ , meaning  $S \cong T$ , a contradiction.
2. Let  $\phi \in \text{Hom}_A(S, T) \setminus \{0\}$ . Then,  $\ker(\phi) \neq S$ , meaning that  $\ker(\phi) = \{0\}$ . Then,  $\text{im}(\phi) = T$ , making  $\phi$  an isomorphism. In particular, this means that  $\phi$  admits an inverse, making  $\text{Hom}_A(S, T)$  a division ring.

□

It turns out we can do a bit better when dealing with a specific class of rings, namely, algebras over fields.

**Theorem 1.3.7** (Schur's Lemmas for Algebras). *Let  $K$  be an algebraically closed field and  $A$  a  $K$ -algebra. Let  $S$  and  $T$  be simple  $A$ -modules.*

1. *If  $S \not\cong T$ , then  $\text{Hom}_A(S, T) = \{0\}$ .*
2. *If  $S \cong T$ , then  $K \cong \text{Hom}_A(S, T)$  via the map  $\alpha \mapsto \alpha \cdot \text{id}$ .*

*Proof.*

1. As before.
2. We do not distinguish  $S$  and  $T$  in this proof.

Fix  $\phi \in \text{Hom}_A(S, S)$ . Then,  $\phi$  can be viewed as an element of  $M_n(K)$ , where  $n = \dim(S)$ . Since  $K$  is algebraically closed,  $\phi$  admits an eigenvalue  $\lambda \in K$ . Now, consider the map  $\phi - \lambda \text{id} \in \text{Hom}_A(S, S)$ . Clearly,  $\ker(\phi - \lambda \text{id}) \neq \{0\}$ , since it contains all eigenvectors with eigenvalue  $\lambda$ . Since  $S$  is simple, it must be that  $\ker(\phi - \lambda \text{id}) = S$ , meaning  $\phi - \lambda \text{id} = 0$ . In other words,  $\phi = \lambda \text{id}$ .

□

We also have a converse when working with algebras.

**Theorem 1.3.8** (Converse of Schur's Lemma for Algebras). *Let  $K$  be a field,  $A$  a  $K$ -algebra and  $M$  a completely reducible  $A$ -module. If  $\text{Hom}_A(M, M) = K$ , then  $M$  is simple.*

*Proof.* sorry

□

**Theorem 1.3.9** (Schur's Lemmas for Finite Groups, over  $\mathbb{C}$ ). *Let  $G$  be a finite group and let  $S$  and  $T$  be simple  $\mathbb{C}G$  modules that are finite-dimensional (as vector spaces) over  $K$ , with associated representations  $\rho_S : G \rightarrow \text{GL}(S)$  and  $\rho_T : G \rightarrow \text{GL}(T)$ . Let  $f : S \rightarrow T$  be an arbitrary  $\mathbb{C}$ -linear map. Define the map*

$$\hat{f} := \frac{1}{|G|} \sum_{g \in G} \rho_T(g) \circ f \circ \rho_S(g^{-1}) \quad (1.3.1)$$

*Then,  $\hat{f}$  is, in fact, a  $\mathbb{C}G$ -module homomorphism. Furthermore, we have the following:*

1. *If  $S \not\cong T$ , then  $\hat{f}$  is identically zero.*
2. *If  $S \cong T$ , then*

$$\hat{f} = \frac{1}{\dim(S)} \text{Tr}(f) \cdot \text{id}_S$$

*Proof.* We only really need to show that  $\hat{f} \in \text{Hom}_{\mathbb{C}G}(S, T)$ . The rest follows relatively naturally

from Theorem 1.3.7 (Schur's Lemmas for Algebras), as we shall see. So, fix  $h \in G$ . Observe that

$$\begin{aligned}
 \rho_T(h) \circ \hat{f} &= \rho_T(h) \left( \frac{1}{|G|} \sum_{g \in G} \rho_T(g) \circ f \circ \rho_S(g^{-1}) \right) \\
 &= \frac{1}{|G|} \sum_{g \in G} \rho_T(hg) \circ f \circ \rho_S(g^{-1}) \circ \rho_S(h^{-1}) \circ \rho_S(h) \\
 &= \frac{1}{|G|} \sum_{g \in G} (\rho_T(hg) \circ f \circ \rho_S(g^{-1}h^{-1})) \circ \rho_S(h) \\
 &= \hat{f} \circ \rho_S(h)
 \end{aligned}$$

proving that  $\hat{f}$  is, indeed, a homomorphism of  $\mathbb{C}G$ -modules. Then,

1. If  $S \not\cong T$ , then by Schur's First Lemma for Algebras,  $\hat{f}$  is identically 0.
2. If  $S \cong T$ , then by Schur's Second Lemma for Algebras,  $\hat{f}$  is a scalar multiple of the identity. Write  $\hat{f} = \lambda \cdot \text{id}_S$ . Clearly, we have that  $\text{Tr}(\hat{f}) = \lambda \dim(S)$ . But, by the definition of  $\hat{f}$ , we have that

$$\begin{aligned}
 \text{Tr}(\hat{f}) &= \frac{1}{|G|} \sum_{g \in G} \text{Tr}(\rho_T(g) \circ f \circ \rho_S(g^{-1})) \\
 &= \frac{1}{|G|} \sum_{g \in G} \text{Tr}(f \circ \rho_T(g) \circ \rho_S(g^{-1})) \\
 &= \frac{1}{|G|} \sum_{g \in G} \text{Tr}(f) = \text{Tr}(f)
 \end{aligned}$$

where we can apply the Trace Theorem to the composition  $\rho_T(g) \circ f \circ \rho_S(g^{-1})$  because  $S \cong T$ , meaning  $\rho_S = \rho_T$  and  $\dim(S) = \dim(T)$  (meaning that we can, indeed, change the order of composition and get a 'sensible' linear map, as all dimensions agree). Since the trace of a linear map is unique, we must have that  $\lambda \cdot \dim(S) = \text{Tr}(f) \iff \lambda = \frac{1}{\dim(S)} \text{Tr}(f)$  (we know  $\dim(S) \neq 0$  because  $S$  is simple). This then tells us that  $\hat{f}$  is of the desired form.

□

Schur's Lemmas (especially the version thereof pertaining to complex representations of finite groups) will prove to be incredibly useful. In the next subsection, we will give a direct application to the classification of representations of finite abelian groups; however, this is not the last that we will be seeing of them.

### 1.3.3 Representations of Finite Abelian Groups over $\mathbb{C}$

It is natural to wonder what the purpose was of studying group algebras and modules. It turns out that one of the reasons the correspondence between representations and group modules is so powerful is that it allows the application of Schur's Lemmas to representation theoretic problems. For instance, in the following Lemma, we classify all irreducible representations of finite abelian groups over  $\mathbb{C}$ .

**Lemma 1.3.10.** *Let  $G$  be a finite abelian group. Then, all irreducible  $\mathbb{C}G$ -modules are of dimension 1. Equivalently, all irreducible representations of  $G$  over  $\mathbb{C}$  are of degree 1.*

*Proof.* Let  $V$  be an irreducible  $\mathbb{C}G$ -module. Since  $G$  is abelian, for all  $g, h \in G$  and  $v \in V$ ,  $(gh) \cdot v = (hg) \cdot v$ . Therefore, for some fixed  $h \in G$ , the following map is  $\mathbb{C}G$ -linear:

$$\phi_h : V \rightarrow V : v \mapsto h \cdot v$$

By Theorem 1.3.9, we know that  $\exists \lambda_h \in \mathbb{C}$  such that  $\widehat{\phi_h} = \phi_h = \lambda_h \cdot \text{id}_V$ . Hence, any subspace of  $V$  must be a  $\mathbb{C}G$ -submodule. But, since  $V$  is irreducible,  $V$  cannot admit any nonzero, proper  $\mathbb{C}G$ -submodules unless  $V$  is of ( $\mathbb{C}$ -)dimension 1.  $\square$

We now have a complete classification of irreducible representations of cyclic groups over  $\mathbb{C}$ .

**Corollary 1.3.11.** *Let  $G = C_n = \langle a \rangle$  be the cyclic group of order  $n$ . Then, there are precisely  $n$  irreducible representations of  $G$  over  $\mathbb{C}$ .*

*Proof.* Let  $G$  be a group and let  $(V, \rho)$  be a representation of  $G$ . We know, from Lemma 1.3.10, that  $V \cong \mathbb{C}$  and hence,  $\text{GL}(V) \cong \mathbb{C}^\times$ . Now, let  $x := \rho(a)$ . It must be that  $x^n = 1$ , making  $x$  an  $n$ th root of unity. In other words,  $\exists 1 \leq k \leq n$  such that  $x = e^{\frac{2\pi i}{k}}$ . Therefore, there are precisely  $n$  possible choices of  $x$ , each giving a different representation.  $\square$

Lemma 1.3.10 is also useful in the study of representations over  $\mathbb{C}$  of arbitrary finite groups.

**Proposition 1.3.12.** *Let  $G$  be a finite group and let  $(V, \rho)$  be a representation of  $G$  over  $\mathbb{C}$ . For all  $g \in G$ , there is a basis of  $V$  with respect to which  $\rho(g)$  has matrix  $\text{diag}(\epsilon_1, \dots, \epsilon_n)$ , with  $\epsilon_i^{\text{ord}(g)} = 1$  for all  $1 \leq i \leq n$ .*

*Proof.* Fix  $g \in G$ , and consider the representation  $\rho' : \langle g \rangle \rightarrow \text{GL}(V)$  given by  $\rho' = \rho|_{\langle g \rangle}$ . Then,  $\rho'$  is a representation of a finite abelian group.

By Maschke's Theorem,  $\rho' = \sigma_1 \oplus \cdots \oplus \sigma_k$  for irreducible subrepresentations  $\sigma_1, \dots, \sigma_m$  of  $\langle g \rangle$ . By Lemma 1.3.10, we know that  $\deg(\sigma_i) = 1$  for each  $i$ , and hence, that  $m = n$ . Picking  $\mathcal{B}$  to be the basis corresponding to this decomposition of  $\rho'$ , we get that the matrix of  $\rho$  with respect to  $\mathcal{B}$  is, indeed, of the desired form.  $\square$

As it turns out, we can combine the theory developed here with the Structure Theorem for Finite Abelian Groups to get an interesting result.

**Lemma 1.3.13.** *Let  $G$  be a finite abelian group, expressed as a product  $C_{n_1} \times \cdots \times C_{n_r}$  of cyclic groups  $C_{n_i}$  of order  $n_i > 1$ . Then,  $G$  has a faithful representation of degree  $r$  over  $\mathbb{C}$ .*

*Proof.* Consider the space  $V = \mathbb{C}^r = \mathbb{C}_1 \oplus \cdots \oplus \mathbb{C}_r$  (where each  $\mathbb{C}_i$  is the one-dimensional subspace spanned by the  $i$ th element of some chosen  $\mathbb{C}$ -basis for  $V$ ). Let  $C_{n_i} = \langle g_i \rangle$  and denote by  $e_i$  the corresponding generators  $(1, \dots, 1, g_i, 1, \dots, 1)$  of  $G$ . Define the map

$$\rho : G \rightarrow \mathbb{C} : e_i \mapsto R_i \quad (1.3.2)$$

where  $R_i$  is the rotation by  $2\pi/n_i$  acting on the subspace  $\mathbb{C}_i \cong \mathbb{C}$ . In other words, with respect to the isomorphism  $\text{GL}(\mathbb{C}_i) \cong \mathbb{C}^\times$ , the map  $R_i$  corresponds to  $\exp(2\pi/n_i)$ .<sup>2</sup>

$\rho$  has the following effect on group elements: for two group elements acting on the same component of  $V$ ,  $\rho$  maps their product to the composition of their associated rotations, and for elements acting on different components,  $\rho$  combines their componentwise actions into a single action across two components. Therefore,  $\rho$  is a group homomorphism, and hence,  $(V, \rho)$  is a representation of  $G$  over  $\mathbb{C}$ .

We now show that  $\rho$  is injective. If  $g \in G$  acts identically on all of  $V$ , it must, in particular, act identically on each component. But, the action of  $g$  on each  $\mathbb{C}_j$  is merely the action of the  $j$ th component of  $g$  on  $\mathbb{C}_j$ . It is easy to see that the componentwise actions of  $\rho$  on  $V$  are all faithful,

<sup>2</sup>To be perfectly precise,  $e_i$  is mapped not to  $R_i$  but to the image of  $R_i$  in the inclusion  $\text{GL}(\mathbb{C}_i) \rightarrow \text{GL}(V)$  that extends  $R_i$  by acting as the identity on components other than  $i$  and as  $R_i$  on component  $i$ . We use the word 'component' to refer to a one-dimensional direct summand  $\mathbb{C}_j$  of  $V$ .

meaning that each component of  $g$  is the identity in its respective cyclic group. Therefore,  $g$  must be the identity in  $G$ , making  $\rho$  a faithful representation.  $\square$

# Chapter 2

## Character Theory

Figure 2.1: The thumbnail of a YouTube video titled "What is Character Theory? | Let's Talk Theory" by Dapper Mr. Tom. The video has nothing to do with mathematics.

In this chapter, we study an important type of functions from groups to fields known as characters. As we shall see, characters encode several useful properties of a group, and have been used extensively to prove several results about finite groups, (the representations of) which are the main object of study in this course. One of the reasons characters are useful to understand representation structures is that they are *class functions*. That is, they encode information not about an individual element of a group but about its conjugacy class, making them good indicators of *structural* and *behavioural* properties. In particular, the character of a representation is independent of the choice of basis of the associated vector space.

Throughout this chapter, we denote by  $G$  an arbitrary finite group.

### 2.1 The Theory of Irreducible Characters

In this section, we give an overview of the theory of irreducible characters. Our approach focuses extensively on the notion of orthogonality with respect to an inner product we shall soon define. An interesting result we will go on to prove is that irreducible characters play an important role in a broader class of functions on groups, telling us that representation theory can be used to study not only groups themselves but also functions thereof.

### 2.1.1 On Central Functions

As we all know, a group can contain several elements that all behave similarly—take, for instance, similar matrices in any general linear group. This is why we have the notion of *conjugacy classes*, which allow us to study the elements of a group in terms of their actions or behaviours.

The purpose of character theory is to understand the structural and behavioural properties of a group, without focusing on syntactic particularities. This is why we define the notion of a *class function*.

**Definition 2.1.1** (Class Function). Let  $X$  be any set. A function  $f : G \rightarrow X$  is said to be a class function if  $f(x) = f(g^{-1}xg)$  for all  $x, g \in G$ —in other words, if it is constant on all conjugacy classes of  $G$ .

In this section, we will primarily be focusing on complex representations. Therefore, the following definition is useful.

**Definition 2.1.2** (Central Function). We say  $f : G \rightarrow \mathbb{C}$  is central if it is a class function. In other words, central functions are precisely  $\mathbb{C}$ -valued class functions.

We are already familiar with several examples of central functions.

**Example 2.1.3** (Examples of Central Functions). The following are all central:

1. The order function  $h \mapsto \text{ord}(h) : H \rightarrow \mathbb{N} \subset \mathbb{C}$  for any group  $H$
2. The determinant function  $A \mapsto \det(A) : \text{GL}(n, \mathbb{C}) \rightarrow \mathbb{C}$  for any  $n \in \mathbb{N}$
3. The trace function  $A \mapsto \text{Tr}(A) : \text{GL}(n, \mathbb{C}) \rightarrow \mathbb{C}$  for any  $n \in \mathbb{N}$

The last two examples are, in particular, compatible with representations of  $G$  over  $\mathbb{C}$ . This will prove to be important when we define the character of a representation. Before doing so, however, we will need to outline the structure of the inner-product space of central functions on  $G$ . First, some notation.

**Notation.** We define

1.  $\mathcal{F}(G, \mathbb{C}) := \{f : G \rightarrow \mathbb{C}\}$
2.  $\mathcal{F}_C(G, \mathbb{C}) := \{f \in \mathcal{F}(G, \mathbb{C}) : f \text{ is central}\}$
3.  $\delta_g(x)$  to be the indicator function (for  $g, x \in G$ ).

We have the following natural result.

**Proposition 2.1.4** ( $\mathbb{C}$ -Vector Space Structure of  $\mathcal{F}(G, \mathbb{C})$  and  $\mathcal{F}_C(G, \mathbb{C})$ ).

1.  $\mathcal{F}(G, \mathbb{C})$  is a  $\mathbb{C}$ -vector space of dimension  $|G|$ , with basis  $\{\delta_g : g \in G\}$ .
2.  $\mathcal{F}_C(G, \mathbb{C})$  is a subspace of  $\mathcal{F}(G, \mathbb{C})$  of dimension equal to the number of conjugacy classes of  $G$ , with basis  $\{\delta_g : g \text{ uniquely represents a conjugacy class of } G\}$ .

*Proof.* The model we choose for this proof is that of  $k^n$  being isomorphic to the set of functions from  $\{1, \dots, n\}$  to  $k$  (for any field  $k$ ). Under this model, the indicator functions on  $\{1, \dots, n\}$  correspond to the standard basis of  $k^n$ .

1. Since  $G$  is finite, this is immediate from the model described above.
2. That  $\mathcal{F}_C(G, \mathbb{C})$  is a subspace follows from the fact that the sum of two central functions is central, as is any scalar multiple of a central function. Furthermore, since central functions are uniquely determined by their values on each conjugacy class,  $\dim(\mathcal{F}_C(G, \mathbb{C}))$  is the number of conjugacy classes of  $G$ .

I also offer a more formal argument here for the dimensionality, as I found it instructive to think about it this way. Let  $C_1, \dots, C_r$  be the conjugacy classes of  $G$ . Write  $C_i = \{g_{i_1}, g_{i_2}, \dots, g_{i_{l_i}}\}$ . Let  $w_i := \sum_{j=1}^{l_i} \delta_{g_{i_j}}$ . It is easy to see that the  $w_i$  are linearly independent: any linear combination of all the  $w_i$  is, in particular, a linear combination of  $\delta_g$  as  $g$  ranges over  $G$ , with each  $\delta_g$  appearing exactly once. Furthermore, the  $w_i$  span  $\mathcal{F}_C(G, \mathbb{C})$ : their span is clearly contained in  $\mathcal{F}_C(G, \mathbb{C})$ , and every element of  $\mathcal{F}_C(G, \mathbb{C})$  must be constant on any given conjugacy class, meaning that the coordinates of conjugate components must be the same.

□

It turns out that there is also a natural inner-product on  $\mathcal{F}(G, \mathbb{C})$ .

**Definition 2.1.5** (Standard Inner-Product on  $\mathcal{F}(G, \mathbb{C})$ ). Define the function  $\langle \cdot, \cdot \rangle : \mathcal{F}(G, \mathbb{C}) \times \mathcal{F}(G, \mathbb{C}) \rightarrow \mathbb{C}$  by

$$\langle f_1, f_2 \rangle = \frac{1}{|G|} \sum_{g \in G} f_1(g) \overline{f_2(g)} \quad (2.1.1)$$

It is easy enough to show that the  $\langle \cdot, \cdot \rangle$  is, indeed, an inner-product on  $\mathcal{F}(G, \mathbb{C})$ . We will also use it as an inner-product on  $\mathcal{F}_C(G, \mathbb{C})$ .

An obvious orthogonal basis for  $\mathcal{F}_C(G, \mathbb{C})$  is that of the indicator functions of representatives of distinct conjugacy classes. However, in this paradigm, the set  $S$  of conjugacy classes of  $G$  merely acts as an *index* set for the standard basis of  $\mathbb{C}^{|S|}$ . I.e, we can infer nothing about  $S$  beyond its size, a quantity that does not tell us about the actual *group* structure of  $G$  (for instance, for any prime  $p$ , the decidedly non-isomorphic abelian groups  $\mathbb{Z}/p^2\mathbb{Z}$  and  $\mathbb{Z}/p\mathbb{Z} \oplus \mathbb{Z}/p\mathbb{Z}$  both have exactly  $p^2$  conjugacy classes). It turns out that we can find a much better orthogonal (indeed, *orthonormal*) basis for  $\mathcal{F}_C(G, \mathbb{C})$  in the world of *characters*, a class of central functions closely related to the group structure of  $G$ .

## 2.1.2 Introduction to Character Theory

In this subsection, we introduce a central function that is compatible with the notion of a representation, namely, the *character*. As we saw in Example 2.1.3, both the trace and the determinant would be good options, but the convention is to define the character in terms of the trace. A heuristic reason is that this way, given characters associated to two representations, their sum will give the character of the direct sum, and their product that of the tensor product of the underlying representations. There are deeper reasons too, which will become clearer as we progress.

**Definition 2.1.6** (Character). Let  $V$  be a  $\mathbb{C}G$ -module. The character of  $V$  is the map  $\chi_V : G \rightarrow \mathbb{C}$  given by  $\chi_V(g) = \text{Tr}(\rho(g))$ , where  $\rho$  is the representation associated to  $V$ .

Immediately, we are able to “import” the following definitions from Chapter 1.

**Definition 2.1.7** (Irreducibility). We say a character  $\chi_V$  is irreducible if the associated represen-

tation  $(V, \rho)$  is irreducible over  $\mathbb{C}$ .

**Definition 2.1.8** (Degree). We define the degree of a character to be that of its associated representation.

**Definition 2.1.9** (Trivial Character). We define the trivial character to be that associated with the trivial representation.

Characters have several important properties, which we list below. We will make extensive use of these properties for the remainder of this chapter.

**Proposition 2.1.10** (On the Behaviour of Characters). *Let  $V$  be a  $\mathbb{C}G$ -module, with associated representation  $\rho$ .*

1. For all  $\mathbb{C}G$ -modules  $W$ ,  $\chi_{V \oplus W} = \chi_V + \chi_W$
2. For all  $\mathbb{C}G$ -modules  $W$ ,  $V \cong W \implies \chi_V = \chi_W$
3.  $\dim(V) = \chi_V(1)$
4. For all  $g \in G$ ,  $\chi_V(g)$  is a sum of  $d$ th roots of unity, where  $d = \text{ord}(g)$ .
5. For all  $g \in G$ ,  $|\chi_V(g)| \leq \dim(V)$ , with equality iff  $g \in \ker(\rho)$ .
6. For all  $g \in G$ ,  $\chi_V(g^{-1}) = \overline{\chi_V(g)}$
7. For all  $\mathbb{C}G$ -modules  $W$ ,  $\chi_{V \otimes W} = \chi_V \cdot \chi_W$

*Proof.* We just give sketches here, not complete proofs.

1. This follows from the fact that the trace of a direct sum is the sum of the traces.
2. This follows from the invariance of the trace under change of basis.
3. This follows from the fact that the trace of the identity is the dimension of the space.
4. For any  $g \in G$  of order  $d$ ,  $\rho(g)$  is of order  $d$ . Hence, its minimal polynomial divides  $X^d - 1 \in \mathbb{C}[X]$ , which has distinct roots in  $\mathbb{C}$ . This means that the eigenvalues of  $\rho(g)$  are  $d$ th roots of unity. Putting  $\rho(g)$  in Jordan Normal Form, we see that its trace is a sum of  $d$ th roots of unity.<sup>1</sup>
5. sorry

<sup>1</sup>It is not necessarily a sum of *all*  $d$ th roots of unity, or even *distinct*  $d$ th roots of unity.

6. sorry

7. Let  $B = \{v_1, \dots, v_n\}$  and  $B' = \{w_1, \dots, w_m\}$  be bases of  $V$  and  $W$  respectively. Denote by  $\rho'$  the representation associated to  $W$ , and fix an arbitrary  $g \in G$ . Let  $(a_{ij})_{1 \leq i, j \leq n}$  be the matrix of  $\rho(g)$  with respect to  $B$ , and let  $(b_{kl})_{1 \leq k, l \leq m}$  be that of  $\rho'(g)$  with respect to  $B'$ . For all  $1 \leq i \leq n$  and  $1 \leq l \leq m$ , we have that

$$\begin{aligned} (\rho \otimes \rho')(g)(v_i \otimes w_l) &= \rho(g)(v_i) \otimes \rho'(g)(w_l) \\ &= \left( \sum_{j=1}^n a_{ij} v_j \right) \otimes \left( \sum_{k=1}^m b_{kl} w_k \right) \\ &= \sum_{j=1}^n \sum_{k=1}^m a_{ij} b_{kl} v_j \otimes w_k \end{aligned}$$

Indeed, the coefficient of  $v_i \otimes w_l$  in the above expression is  $a_{ii} b_{ll}$ , telling us that rest is easy.

□

We now give a few examples of characters of representations.

**Example 2.1.11** (The Dihedral Group of Order 8). Let  $G = D_8$ , the dihedral group of order 8. Consider the presentation

$$G = \langle a, b \mid a^4 = b^2 = 1, b^{-1}ab = a^{-1} \rangle$$

Let  $\rho : G \rightarrow \text{GL}(2, \mathbb{C})$  be a representation of  $G$  over  $\mathbb{C}$  given by

$$\rho(a) = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \quad \text{and} \quad \rho(b) = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$$

The associated character  $\chi_V$  then takes on the following values:

$g$	1	$a$	$a^2$	$a^3$	$b$	$ab$	$a^2b$	$a^3b$
$\rho(g)$	$\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$	$\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}$	$\begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix}$	$\begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}$	$\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$	$\begin{bmatrix} 0 & -1 \\ -1 & 0 \end{bmatrix}$	$\begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix}$	$\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$
$\chi_V(g)$	2	0	-2	0	0	0	0	0

One can show the conjugacy classes of  $D_8$  to be precisely  $\{1\}$ ,  $\{a, a^3\}$ ,  $\{a^2\}$ ,  $\{b, a^2b\}$ , and  $\{ab, a^3b\}$ . From the table above, it is clear that conjugate elements do, indeed, have the same character value. Therefore, for the sake of brevity, one typically only lists the values of a character

corresponding to the representatives of its conjugacy classes.

**Example 2.1.12** (The Cyclic Group of Order 3). Let  $G = C_3 = \langle a \rangle$  be the cyclic group of order 3. By Corollary 1.3.11, we know that  $G$  admits exactly three irreducible representations over  $\mathbb{C}$ , all of degree 1, each corresponding to choice of 3rd root of unity to which to send  $a$ . Denote these by  $\rho_1$ ,  $\rho_2$  and  $\rho_3$ , so that  $\rho_j(a) = e^{\frac{2\pi i(j-1)}{3}}$  for  $j = 1, 2, 3$ . Denote their corresponding (irreducible) characters  $\chi_1$ ,  $\chi_2$  and  $\chi_3$ . Since the trace map is simply the constant map on a space of dimension 1, we have the following values for the characters:

$g$	1	$a$	$a^2$
$\chi_1(g)$	1	1	1
$\chi_2(g)$	1	$e^{\frac{2\pi i}{3}}$	$e^{\frac{4\pi i}{3}}$
$\chi_3(g)$	1	$e^{\frac{4\pi i}{3}}$	$e^{\frac{2\pi i}{3}}$

In the above example, we see that the characters of the irreducible representations of  $G$  form an orthonormal system with respect to the standard inner-product (2.1.1)—for instance,  $\chi_1 \neq \chi_2$ , and clearly,

$$\begin{aligned}
 \langle \chi_1, \chi_2 \rangle &= \frac{1}{3} \sum_{g \in G} \chi_1(g) \overline{\chi_2(g)} \\
 &= \frac{1}{3} \left( 1 + e^{\frac{2\pi i}{3}} + e^{\frac{4\pi i}{3}} \right) \\
 &= \frac{1}{3} \left( 1 + e^{\frac{4\pi i}{3}} + e^{\frac{2\pi i}{3}} \right) = 0
 \end{aligned}$$

whereas  $\langle \chi_1, \chi_1 \rangle = 1$ . In similar fashion, one can check the remaining 7 cases to show that  $\langle \chi_i, \chi_j \rangle = \delta_{ij}$  for  $i, j = 1, 2, 3$ . It turns out that this is merely one instance of a more general orthogonality phenomenon. We will understand this better in the next subsection.

### 2.1.3 The Orthogonality Theorem

In this subsection, we dive into the heart of Character Theory, proving one of the most fundamental results in the field: the Orthogonality Theorem. This theorem generalises the orthogonality that we observed in Example 2.1.12, and has several important consequences, most notably the fact that the irreducible characters of a group form an orthonormal basis for the space of class functions on that group, a result we will see in the next subsection.

First, we state and prove a useful lemma that helps us understand the *matrices* of irreducible representations (taken, as per convention, with respect to the standard basis of  $\mathbb{C}^n$ ). The point of this is that matrices are more computation-friendly.

**Lemma 2.1.13.** *Let  $\rho : G \rightarrow \mathrm{GL}(n, \mathbb{C})$  and  $\rho' : G \rightarrow \mathrm{GL}(m, \mathbb{C})$  be irreducible representations of  $G$  over  $\mathbb{C}$ . Fix  $j, s \in \{1, \dots, m\}$  and  $r, i \in \{1, \dots, n\}$ .*

1. *If  $\rho$  and  $\rho'$  are not equivalent, then*

$$\frac{1}{|G|} \sum_{g \in G} [\rho(g)]_{ri} [\rho'(g^{-1})]_{js} = 0$$

2. *If  $\rho$  and  $\rho'$  are equivalent, then*

$$\frac{1}{|G|} \sum_{g \in G} [\rho(g)]_{ri} [\rho'(g^{-1})]_{js} = \begin{cases} \frac{1}{n} & \text{if } i = j \text{ and } r = s \\ 0 & \text{otherwise} \end{cases}$$

where we use the notation  $[T]_{ij}$  to refer to the  $ij$ th entry of the matrix of any  $T \in \mathrm{GL}(n, \mathbb{C})$  with respect to the standard basis of  $\mathbb{C}^n$ .

*Proof.* Let  $V = \mathbb{C}^n$  and  $W = \mathbb{C}^m$  be the two simple  $\mathbb{C}G$ -modules corresponding to  $\rho$  and  $\rho'$  respectively. The idea is to define a linear map that will allow us to use Schur's Lemmas—specifically, those pertaining to finite groups over  $\mathbb{C}$  (see Theorem 1.3.9).

Let  $\phi_{ij} : W \rightarrow V$  be the  $\mathbb{C}$ -linear map given by the  $n \times m$  matrix (with respect to the standard bases of  $V$  and  $W$ ) with  $ij$ th entry 1 and all other entries 0. In other words, let  $\phi_{ij}$  denote the  $ij$ th element of the standard basis of the space of linear maps from  $V$  to  $W$ . Define

$$\widehat{\phi}_{ij} := \frac{1}{|G|} \sum_{g \in G} \rho(g) \circ \phi_{ij} \circ \rho'(g^{-1})$$

By Theorem 1.3.9,  $\widehat{\phi}_{ij}$  is a  $\mathbb{C}G$ -module homomorphism from  $W$  to  $V$ . Indeed, we have that

$$\begin{aligned} [\widehat{\phi}_{ij}]_{rs} &= \left[ \frac{1}{|G|} \sum_{g \in G} \rho(g) \circ \phi_{ij} \circ \rho'(g^{-1}) \right]_{rs} \\ &= \frac{1}{|G|} \sum_{g \in G} [\rho(g) \circ \phi_{ij} \circ \rho'(g^{-1})]_{rs} \end{aligned}$$

$$\begin{aligned}
&= \sum_{k=1}^n \sum_{l=1}^m \frac{1}{|G|} \sum_{g \in G} [\rho(g)]_{rk} [\phi_{ij}]_{kl} [\rho'(g^{-1})]_{ls} \\
&= \frac{1}{|G|} \sum_{g \in G} [\rho(g)]_{ri} [\rho'(g^{-1})]_{js}
\end{aligned}$$

1. If  $W \not\cong V$ , we have  $\widehat{\phi}_{ij} = 0$ . In particular,

$$\frac{1}{|G|} \sum_{g \in G} [\rho(g)]_{ri} [\rho'(g^{-1})]_{js} = [\widehat{\phi}_{ij}]_{rs} = 0$$

2. Similarly, if  $W \cong V$ , we have  $m = n$ . Now, by Theorem 1.3.9, we know that

$$\widehat{\phi}_{ij} = \frac{1}{n} \text{Tr}(\phi_{ij}) \cdot \text{id}_V = \frac{1}{n} \delta_{ij} \cdot \text{id}_V$$

We then have that

$$[\rho(g)]_{ri} [\rho'(g^{-1})]_{js} = [\widehat{\phi}_{ij}]_{rs} = \begin{cases} \frac{1}{n} & \text{if } i = j \text{ and } r = s \\ 0 & \text{otherwise} \end{cases}$$

□

*Remark.* As per Dr. Rizzoli, on the exam, it's more important to know the idea of such a proof than the specifics of *which index goes where*.

It turns out that by simply unfolding a few definitions and playing with the order of summations, we can use the above lemma to prove the Orthogonality Theorem.

**Theorem 2.1.14** (Orthogonality Theorem). *Let  $S, T$  be irreducible  $\mathbb{C}G$ -modules.*

1. *If  $S \not\cong T$ , then  $\langle \chi_S, \chi_T \rangle = 0$ .*

2. *If  $S \cong T$ , then  $\langle \chi_S, \chi_T \rangle = 1$ .*

*In other words, irreducible characters form an orthogonal system.*

*Proof.* Let  $P : G \rightarrow \text{GL}(n, \mathbb{C})$  and  $Q : G \rightarrow \text{GL}(m, \mathbb{C})$  be the representations corresponding to  $S$  and  $T$ . We know that

$$\langle \chi_S, \chi_T \rangle = \frac{1}{|G|} \sum_{g \in G} \chi_S(g) \chi_T(g^{-1})$$

$$\begin{aligned}
&= \frac{1}{|G|} \sum_{g \in G} \text{Tr}(P(g)) \text{Tr}(Q(g^{-1})) \\
&= \frac{1}{|G|} \sum_{g \in G} \left( \sum_{i=1}^n [P(g)]_{ii} \right) \left( \sum_{j=1}^n [Q(g^{-1})]_{jj} \right) \\
&= \sum_{i=1}^n \sum_{j=1}^m \frac{1}{|G|} \sum_{g \in G} [P(g)]_{ii} [Q(g^{-1})]_{jj}
\end{aligned}$$

We can now use Lemma 2.1.13 to evaluate this sum.

1. If  $S \not\cong T$ , then

$$\frac{1}{|G|} \sum_{g \in G} [P(g)]_{ii} [Q(g^{-1})]_{jj} = 0$$

for all  $1 \leq i \leq n$  and  $1 \leq j \leq m$ . Hence,

$$\langle \chi_S, \chi_T \rangle = \sum_{i=1}^n \sum_{j=1}^m 0 = 0$$

2. If  $S \cong T$ , then first of all,  $n = m$ . Indeed,

$$\frac{1}{|G|} \sum_{g \in G} [P(g)]_{ii} [Q(g^{-1})]_{jj} = \begin{cases} \frac{1}{n} & \text{if } i = j \\ 0 & \text{otherwise} \end{cases}$$

for all  $1 \leq i, j \leq n$ . Hence,

$$\langle \chi_S, \chi_T \rangle = \sum_{i=1}^n \sum_{j=1}^n \frac{1}{n} \delta_{ij} = \sum_{i=1}^n \frac{1}{n} = 1$$

□

We have the following important corollary.

**Corollary 2.1.15.** *Up to isomorphism, there are finitely many irreducible  $\mathbb{C}G$ -modules.*

*Proof.* Suppose there exist infinitely many, pairwise nonisomorphic  $\mathbb{C}G$ -modules. Then, the (infinite) subset of  $\mathcal{F}(G, \mathbb{C})$  consisting of all of their characters would be pairwise orthogonal (by Theorem 2.1.14). Since orthogonality implies linear independence, this set would need to be contained in a basis of  $\mathcal{F}(G, \mathbb{C})$ . However, by Proposition 2.1.4, such a basis would need to be finite,

leading to a clear contradiction. Hence, there can only exist finitely many  $\mathbb{C}G$ -modules (up to isomorphism).  $\square$

### 2.1.4 Understanding Irreducible Characters

In this subsection, we will explore the properties of irreducible characters in more detail. In particular, we will see that they form a basis for the space of class functions on  $G$ . This is a very important result, which illustrates the power of character theory in understanding the properties of a group. We will begin by introducing some notation and stating a few basic properties of irreducible characters that will be useful in the proof of the main result.

**Notation** (Irreducible Characters). Denote by  $\text{Irr}(G)$  the subset of  $\mathcal{F}_C(G, \mathbb{C})$  consisting of irreducible characters of  $G$ .

The Orthogonality Theorem tells us the following facts about Irreducible Characters.

**Proposition 2.1.16** (On the Behaviour of Irreducible Characters).

1.  $\text{Irr}(G)$  is a linearly independent set. In particular,  $|\text{Irr}(G)| \leq |G|$ .
2. Let  $V = V_1 \oplus \cdots \oplus V_r$  be a  $\mathbb{C}G$  module, with  $V_i$  simple for  $1 \leq i \leq r$ . For any simple  $\mathbb{C}G$  module  $S$ , the number of  $V_i$ s isomorphic to  $S$ , known as the multiplicity of  $S$ , is given by  $\langle \chi_V, \chi_S \rangle$ .
3. Let  $V, V'$  be simple  $\mathbb{C}G$ -modules. Then,  $V \cong V' \iff \chi_V = \chi_{V'}$ .
4. A  $\mathbb{C}G$ -module  $V$  is simple iff  $\langle \chi_V, \chi_V \rangle = 1$ .

*Proof.*

1. The linear independence follows immediately from the fact that  $\text{Irr}(G)$  form an orthonormal system. The inequality follows from the fact that all central functions are class functions: they agree for all conjugate elements of  $G$ . This means that  $\dim(\mathcal{F}_C(G, \mathbb{C}))$  is simply the number of conjugacy classes of  $G$ . Since  $\dim(\mathcal{F}_C(G, \mathbb{C}))$  must be at least  $|\text{Irr}(G)|$  and the number of conjugacy classes of  $G$  must be at most  $|G|$ , we have the desired result.

2. We know, from Proposition 2.1.10, that  $\chi_V = \chi_{V_1} + \cdots + \chi_{V_r}$ . So,

$$\begin{aligned}\langle \chi_V, \chi_S \rangle &= \langle \chi_{V_1} + \cdots + \chi_{V_r}, \chi_S \rangle \\ &= \sum_{i=1}^r \langle \chi_{V_i}, \chi_S \rangle\end{aligned}$$

Observe that for  $1 \leq i \leq r$ ,  $\langle \chi_{V_i}, \chi_S \rangle = 1$  if  $V_i \cong S$  and 0 otherwise. Hence, the only nonzero terms in the summation are given by those  $i$  for which  $V_i \cong S$ . Since all of those terms are 1, the sum must evaluate to the multiplicity of  $S$ .

3. ( $\implies$ ) This is true regardless of the simplicity of  $V$  and  $V'$  (cf. Proposition 2.1.10).

( $\impliedby$ ) This turns out to be a straightforward application of the previous part. Let  $W = V \oplus V'$ . Then, the multiplicity of  $V$  is given by

$$\langle \chi_W, \chi_V \rangle = \langle \chi_V + \chi_{V'}, \chi_V \rangle = \langle \chi_V, \chi_V \rangle + \langle \chi_{V'}, \chi_V \rangle = 2 \langle \chi_V, \chi_V \rangle = 2$$

This means that there are two terms in the decomposition  $W = V \oplus V'$  that are isomorphic to  $V$ , which is only possible if  $V \cong V'$ .

4. ( $\implies$ ) This follows immediately from the Orthogonality Theorem.

( $\impliedby$ ) Let  $\text{Irr}(G) = \{\chi_1, \dots, \chi_r\}$ , with corresponding simple  $\mathbb{C}G$ -modules  $\{V_1, \dots, V_r\}$ . Denoting by  $a_i$  the multiplicity of each  $V_i$  in  $V$ , we have that

$$V = V_1^{\oplus a_1} \oplus \cdots \oplus V_r^{\oplus a_r}$$

where we use the notation  $V_i^{\oplus a_i}$  to mean  $\underbrace{V_i \oplus \cdots \oplus V_i}_{a_i \text{ times}}$ , allowing  $a_i = 0$ .

We then have

$$\begin{aligned}\chi_V &= \sum_{i=1}^r a_i \chi_i \\ \implies \langle \chi_V, \chi_V \rangle &= \sum_{i=1}^r a_i^2\end{aligned}$$

by the Orthogonality Theorem. Since  $\langle \chi_V, \chi_V \rangle = 1$ , it must be that only one of the  $a_i$ s is nonzero, and equal to 1. Hence,  $V = V_i$  for this  $i$ , making  $V$  simple.

□

We now have everything we need to prove the following important theorem.

**Theorem 2.1.17.**  *$\text{Irr}(G)$  is a basis for  $\mathcal{F}_C(G, \mathbb{C})$ .*

*Proof.* As  $\text{Irr}(G)$  is linearly independent, we only need to show that it spans  $\mathcal{F}_C(G, \mathbb{C})$ . To that end, let  $W = \text{Span}(\text{Irr}(G)) \leq \mathcal{F}_C(G, \mathbb{C})$ , with orthogonal complement  $W^\perp$  with respect to the inner-product (2.1.1). Since  $V = W \oplus W^\perp$ , if we can show that  $W^\perp = \{0\}$ , we would have that  $V = W$ , proving the desired result.

Fix  $f \in W^\perp$ , and consider the element  $\hat{f} \in \mathbb{C}G$  given by

$$\hat{f} = \sum_{g \in G} \overline{f(g)} \cdot g$$

Our approach will be to consider the action of  $\hat{f}$  by scalar multiplication on simple  $\mathbb{C}G$ -modules. We will show this to be a  $\mathbb{C}G$ -module homomorphism, compute its trace, and apply the Orthogonality Theorem to show that  $f$  must be identically zero.

First, we show that  $\hat{f} \in Z(\mathbb{C}G)$ —ie, that  $\hat{f}$  commutes (multiplicatively) with all elements of  $\mathbb{C}G$ . To show this, it suffices to show that  $h^{-1}\hat{f}h = \hat{f}$  for all  $h \in G$  (ie, that  $\hat{f}$  commutes with all elements of  $G$ ). To that end, fix  $h \in G$ . Then,

$$\begin{aligned} h^{-1}\hat{f}h &= \sum_{g \in G} \overline{f(g)} \cdot h^{-1}gh \\ &= \sum_{g \in G} \overline{f(h^{-1}gh)} \cdot h^{-1}gh \\ &= \hat{f} \end{aligned}$$

where the first equality follows from the fact that  $\overline{f(g)} \in \mathbb{C}$ , thereby commuting with all elements of  $g$  in  $\mathbb{C}G$ ; the second equality from the fact that  $f$  is central (recall that  $W, W^\perp \leq \mathcal{F}_C(G, \mathbb{C})$ ); and last equality from a change of variables in the summation, replacing  $g$  with  $hgh^{-1}$ . The fact that  $\hat{f} \in Z(\mathbb{C}G)$  will prove useful in the next step of the proof.

Now, let  $S$  be any simple  $\mathbb{C}G$ -module. Consider the  $\mathbb{C}$ -linear map  $\phi : S \rightarrow S$  given by

$$\phi(v) = \hat{f} \cdot v = \sum_{g \in G} \overline{f(g)} \cdot (g \cdot v)$$

where  $g \cdot v$  refers to the action of  $g$  on  $S$  given by its  $\mathbb{C}G$ -module structure<sup>2</sup>. In the notation of (1.3.1), consider the map  $\hat{\phi} : S \rightarrow S$ . Since  $\hat{f} \in Z(\mathbb{C}G)$ , we have that for all  $v \in V$ ,

$$\begin{aligned} \hat{\phi}(v) &= \frac{1}{|G|} \sum_{g \in G} g \cdot \phi(g^{-1} \cdot v) \\ &= \frac{1}{|G|} \sum_{g \in G} g \hat{f} g^{-1} \cdot v \\ &= \frac{1}{|G|} \sum_{g \in G} \hat{f} \cdot v \\ &= \hat{f} \cdot v = \phi(v) \end{aligned}$$

It follows from Theorem 1.3.9 that

$$\phi = \hat{\phi} = \frac{\text{Tr}(\phi)}{\dim(S)} \cdot \text{id}$$

Our next step will be to show that  $\phi$  is identically zero. We will do this by computing its trace and showing it to be zero.<sup>3</sup> Denote by  $\rho_S$  the (irreducible) representation corresponding to  $S$  and by  $\chi_S$  its corresponding character. Then, as per the definition of  $\phi$ , we have that

$$\begin{aligned} \text{Tr}(\phi) &= \text{Tr} \left( \sum_{g \in G} \overline{f(g)} \cdot \rho_S(g) \right) \\ &= \sum_{g \in G} \overline{f(g)} \cdot \text{Tr}(\rho_S(g)) \\ &= \sum_{g \in G} \overline{f(g)} \cdot \chi_S(g) \end{aligned}$$

Observe that the above expression is merely  $|G|$  times the inner-product of  $f$  and  $\chi_S$  (cf.

<sup>2</sup>ie, if  $\rho_S$  is the representation corresponding to  $S$ , then  $g \cdot v$  corresponds to  $\rho_S(g)(v)$

<sup>3</sup>Indeed, a trace zero map is not, in general, the zero map; this is where the computation involving Schur's Lemmas plays a crucial role. As we have shown  $\phi$  to be given by the action of scalar multiplication by its trace (divided by some nonzero factor, which is irrelevant for our purposes), if we can show its trace to be zero, we will have shown that  $\phi$  itself is identically zero.

(2.1.1)). Since  $f \in W^\perp$  and  $\chi_S \in W$ , we must have that

$$\text{Tr}(\phi) = |G| \langle \chi_S, f \rangle = 0$$

proving that in fact,  $\phi = 0$ .

It remains to show that  $f = 0$ . To that end, consider  $V = \mathbb{C}G$  as a  $\mathbb{C}G$ -module<sup>4</sup>. Let

$$\mathbb{C}G = S_1 \oplus \cdots \oplus S_r$$

be its decomposition into simple  $\mathbb{C}G$ -modules. By the above computations, we know that the maps  $\phi_i : S_i \rightarrow S_i$  given by  $\phi_i(v) = \hat{f} \cdot v$  are all zero. In particular, for  $i$  such that  $1 \in S_i$  (with  $1$  being the multiplicative identity of  $\mathbb{C}G$ ), we have that

$$\begin{aligned} 0 = \phi_i(1) &= \hat{f} \cdot 1 = \hat{f} \\ &= \sum_{g \in G} \overline{f(g)} \cdot g \end{aligned}$$

Since  $G \subset \mathbb{C}G$  is a  $\mathbb{C}$ -basis of  $\mathbb{C}G$ , in particular, the elements of  $G$  are linearly independent over  $\mathbb{C}$ . This means that the only way the above sum can be zero is if  $\overline{f(g)} = 0$  for all  $g \in G$ . Since  $f$  was arbitrary, we have that  $W^\perp = \{0\}$ , proving the desired result.  $\square$

*Remark.* The above proof illustrates the power of several concepts we have learnt so far.

1. The  $\mathbb{C}G$ -module-formulation of a representation allowed us to simplify notation by constructing  $\hat{f}$  as a (central) element of  $\mathbb{C}G$ , making it correspond effectively to a (central) element of  $\text{GL}(V)$  for *any* representation  $V$  of  $G$ .
2. The semi-simplicity of  $\mathbb{C}G$  as a  $\mathbb{C}G$ -module (ie, the complete reducibility of the regular representation) allowed us to apply a result on simple  $\mathbb{C}G$ -modules to study the properties of  $G$  itself. In particular, by reducing to the case of simple  $\mathbb{C}G$ -modules, we were able to apply Schur's Lemmas.
3. Schur's Lemmas allowed us to express  $\phi$  in a more convenient form, whereby we could simplify the problem of showing  $\phi$  to be zero to that of showing its trace to be zero.

---

<sup>4</sup>Recall that this corresponds to the regular representation.

## 2.2 Character Tables

### 2.2.1 The Orthogonality Relations

For the purposes of this subsection, let  $C_1, \dots, C_k$  be the conjugacy classes of  $G$  with representatives  $g_1, \dots, g_k$  respectively. Recall that by the Orbit-Stabiliser Theorem,

$$|C_i| = \frac{|G|}{|C_G(g_i)|}$$

where  $C_G(\cdot)$  refers to the centraliser<sup>5</sup> of an element in  $G$ . Now, let  $\text{Irr}(G) = \{\chi_1, \dots, \chi_k\}$ .

**Definition 2.2.1** (Character Table). A character table is a  $k \times k$  table whose columns are the conjugacy classes (or their representatives) and whose rows are the irreducible characters. In other words, it is a table whose  $(i, j)$ th entry is  $\chi_i(g_j)$ .

We now have the following important result that lets us check orthogonality as we go across the columns.

**Proposition 2.2.2** (First Orthogonality Relation). *Given  $1 \leq r, s \leq k$ , we have*

$$\frac{1}{|G|} \sum_{j=1}^k |C_j| \chi_r(g_j) \chi_s(g_j^{-1}) = \delta_{rs}$$

*Proof.* Observe that

$$\begin{aligned} \delta_{rs} &= \langle \chi_r, \chi_s \rangle \\ &= \frac{1}{|G|} \sum_{g \in G} \chi_r(g) \chi_s(g^{-1}) \\ &= \frac{1}{|G|} \sum_{j=1}^k \left( \sum_{g \in C_j} \chi_r(g) \chi_s(g^{-1}) \right) \\ &= \frac{1}{|G|} \sum_{j=1}^k |C_j| \chi_r(g_j) \chi_s(g_j^{-1}) \end{aligned}$$

where the last inequality follows from the fact that characters are central (ie, they are equal for all

---

<sup>5</sup>Recall that the centraliser of a group element is the set of all elements that commute with it.

elements of a conjugacy class).

□

We can use this to prove an important result about the regular representation.

**Theorem 2.2.3.** *Let  $\chi_{\text{reg}}$  denote the character of the regular representation of  $G$  over  $\mathbb{C}$ . Then,*

$$\chi_{\text{reg}} = \sum_{j=1}^k \chi_j(1) \chi_j$$

*Proof.* sorry

□

**Corollary 2.2.4.**  $\sum_{i=1}^k (\chi_i(1))^2 = |G|$ .

*Proof.*  $\chi_{\text{reg}}(1) = \sum_{i=1}^k (\chi_i(1))^2 = |G|$ .

□

We now have a similar result about going down the rows.

**Proposition 2.2.5** (Second Orthogonality Relation). *Given  $1 \leq r, s \leq k$ , we have*

$$\sum_{i=1}^k \chi_i(g_r) \chi_i(g_s^{-1}) = \begin{cases} 0 & \text{if } r \neq s \\ |C_G(g_r)| & \text{if } r = s \end{cases}$$

*Proof.* Let  $A$  be the matrix  $(A_{ij})_{ij}$ , where  $A_{ij} := \chi_i(g_j)$ . Similarly, let  $B$  be the matrix  $(B_{ij})_{ij}$ , where  $B_{ij} := \frac{|C_i|}{|G|} \chi_j(g_i^{-1})$ . Then, writing  $AB = (AB)_{pq}$ , we have

$$\begin{aligned} (AB)_{pq} &= \sum_{l=1}^k A_{pl} B_{lq} \\ &= \sum_{l=1}^k \chi_p(g_l) \frac{|C_l|}{|G|} \chi_q(g_l^{-1}) \\ &= \langle \chi_p, \chi_q \rangle = \delta_{pq} \end{aligned}$$

This proves that in fact,  $AB = I$ , the identity matrix. This, in particular, means that  $BA = I$  as well. It turns out that setting  $\delta_{pq} = (BA)_{pq}$  gives us the desired result.

□

## 2.2.2 Character Tables of Symmetric Groups

**Example 2.2.6** ( $S_3$ ).  $S_3$  has precisely three conjugacy classes  $C_1$ ,  $C_2$  and  $C_3$  with representatives  $g_1 = 1$ ,  $g_2 = (12)$  and  $g_3 = (123)$ . We then have the following character table for  $S_3$ :

	1	(12)	(123)
$\chi_1$	1	1	1
$\chi_2$	1	-1	1
$\chi_3$	2	0	-1

Here,  $\chi_1$  corresponds to the trivial representation (of degree 1),  $\chi_2$  to the sign representation (of degree 1), and  $\chi_3$  to the subrepresentation  $W = \text{Span}(e_1 - e_2, e_1 - e_3)$  (of degree 2) of the permutation representation on  $\mathbb{C}^3$ . Note that all of these representations are irreducible, the first two because their degrees are 1, and the third because we can show  $\langle \chi_W, \chi_W \rangle$  to be equal to 1 (cf. the fourth point of Proposition 2.1.16).

**Example 2.2.7** ( $S_4$ ). Observe that the conjugacy classes  $C_i$ ,  $i = 1, \dots, 5$ , of  $S_4$  correspond precisely to the various possible cycle shapes. They therefore have representatives  $g_1 = 1$ ,  $g_2 = (12)$ ,  $g_3 = (123)$ ,  $g_4 = (12)(34)$ , and  $g_5 = (1234)$ . The conjugacy classes have sizes 1, 6, 8, 3 and 6 respectively.

We then have the following character table for  $S_4$ :

	1	(12)	(123)	(12)(34)	(1234)
$\chi_1$	1	1	1	1	1
$\chi_2$	1	-1	1	1	-1
$\chi_3$	3	1	0	-1	-1
$\chi_4$	2	0	-1	2	0
$\chi_5$	$a$	$b$	$c$	$d$	$e$

where the characters  $\chi_i$  are as follows:

1.  $\chi_1$  is the trivial character.
2.  $\chi_2$  is the sign character<sup>a</sup>.
3.  $\chi_3$  is the deleted permutation character given by the subrepresentation of the permutation representation<sup>b</sup> of  $S_4$  corresponding to  $\text{Span}(e_1 - e_2, e_2 - e_3, e_3 - e_4)$ , an  $S_4$ -invariant subspace of  $\mathbb{C}^4$ .

4.  $\chi_4$  is given by the following construction. Consider

$$N = \{1, (12)(34), (13)(24), (14)(23)\} \trianglelefteq S_4$$

One can show that  $S_4/N \cong S_3$ . Let  $\pi : S_4 \twoheadrightarrow S_3$  be the associated quotient map. Then, if  $\rho : S_3 \rightarrow \text{GL}(2, \mathbb{C})$  is a 2-dimensional irreducible representation of  $S_3$ , then the map  $\rho' := \rho \circ \pi : S_4 \rightarrow \text{GL}(2, \mathbb{C})$  is also irreducible. We take  $\chi_4$  to be the associated character.

5.  $\chi_5$  is the regular character<sup>c</sup>. We can actually solve for  $a, b, c, d, e$  using the Orthogonality Relations. From Corollary 2.2.4, we know that

$$1 + 1 + 9 + 4 + a^2 = 24 = |S_4|$$

from which we can conclude that  $a = 3$ . Then, using the First Orthogonality Relation (Proposition 2.2.2), we can see that

$$1 - 1 + 3 + 0 + ab = 0$$

from which we can conclude that  $b = -1$ .

sorry

---

<sup>a</sup>ie, that corresponding to the sign representation

<sup>b</sup>ie, that corresponding to its action on  $\mathbb{C}^4$  by permuting the standard basis

<sup>c</sup>ie, that corresponding to the regular representation

Note that the number of irreducible characters of degree 1 of any group  $G$  is  $|G|/|G'|$ , where  $G'$  is the derived subgroup of  $G$ . Indeed, there is a one-to-one correspondence between degree 1 irreducible characters of  $G$  and those of  $G/G'$ .

It turns out that we can glean even more information about groups from their characters, for which we will need the properties of the algebraic integers.

## 2.3 Integrality

### 2.3.1 The Algebraic Integers

First, we recall the notion of integrality over an integral domain.

**Definition 2.3.1** (Integrality). Let  $R$  be an integral domain, and  $S \supset R$  an extension. We say that  $s \in S$  is integral over  $R$  if one of the following equivalent conditions is satisfied:

- $s$  is a root of a monic polynomial in  $R[X]$ .
- The minimal polynomial of  $s$  over  $\text{Frac}(R)$  is actually in  $R[X]$ .

We now define what it means for a complex number to be an algebraic integer.

**Definition 2.3.2** (Algebraic Integer). We say that a number  $\alpha \in \mathbb{C}$  is an algebraic integer if it is integral over  $\mathbb{Z}$ .

**Notation.** Given a conjugacy class  $C$  of  $G$ , we define

$$\hat{C} := \sum_{g \in C} g \quad (2.3.1)$$

to be an element of  $\mathbb{C}G$ .

**Lemma 2.3.3.** Let  $g \in G$  and let  $C = g^G$ . Let  $S$  be a simple  $\mathbb{C}G$ -module. Then, for all  $s \in S$ , we have an action by scalar multiplication

$$\hat{C} \cdot s = \lambda s$$

$$\text{where } \lambda = \frac{|C|}{|C_G(g)|} \frac{\chi(g)}{\chi_s(1)} = |C| \frac{\chi_s(g)}{\chi_s(1)}.$$

*Proof.* Define a function  $\phi : S \rightarrow S : s \mapsto \hat{C} \cdot s$ . Since  $\hat{C} \in Z(\mathbb{C}G)$ , we have that  $\forall x \in G$ ,  $x \cdot \phi(s) = \phi(x \cdot s)$ . This makes  $\phi$  a  $\mathbb{C}G$ -module homomorphism. Then, by Schur's Lemmas, we know that  $\phi = \lambda \text{id}$ . This means that... □

**Lemma 2.3.4.** Let  $r = \sum_{g \in G} \alpha_g g$  for some  $\alpha_g \in \mathbb{Z}$ . Suppose that  $\exists \lambda, v \in \mathbb{C}G \setminus \{0\}$  such that  $rv = \lambda v$ . Then,  $\lambda$  is an algebraic integer.

*Proof.* Let  $G = \{g_1, \dots, g_n\}$ . For all  $1 \leq i \leq n$ ,

$$rg_i = \sum_{j=1}^n \alpha_{ij} g_j$$

The key observation here is that  $\alpha_{ij} \in \mathbb{Z}$  for all  $1 \leq i, j \leq n$ . Then, if  $rv = \lambda v$ , we have that  $\lambda$  is an eigenvalue of the matrix  $A := (\alpha_{ij})_{1 \leq i, j \leq n} \in M_{n \times n}(\mathbb{Z})$ . This makes  $\lambda$  a root of the characteristic polynomial of  $A$  (over  $\mathbb{Z}$ ), which is monic and of degree  $n$ .  $\square$

The point of lemmas 1 and 2 is the following Corollary, the proof of which is trivial:

**Corollary 2.3.5.** *For any  $\chi \in \text{Irr}(G)$  and  $g \in G$ , the quantity  $\lambda = \frac{|G|}{|C_G(g)|} \frac{\chi(g)}{\chi(1)}$  is an algebraic integer.*

This leads us to the following important connection between algebraic integers and irreducible representations.

**Theorem 2.3.6.** *For all  $\chi \in \text{Irr}(G)$ ,  $\chi(1) \mid |G|$ .*

*Proof.* Check phone  $\square$

## 2.3.2 The $n$ th Roots of Unity

**Lemma 2.3.7.** *Let  $w$  be an  $n$ th root of unity in  $\mathbb{C}$ . Then,*

$$\sum_{1 \leq i \leq m, (i, n)=1} w^i \in \mathbb{Z}$$

*Proof.* EXERCISE. Hint: induction on  $n$ .  $\square$

**Proposition 2.3.8.** *Let  $g \in G$  be of order  $n$ . Suppose that  $g^i$  is conjugate to  $g$  for all  $1 \leq i \leq n$  such that  $(i, n) = 1$ . Then, for all characters  $\chi$  of  $G$ ,  $\chi(g)$  is an integer.*

*Proof.* Let  $\chi$  be a character of  $G$ , with associated representation  $(V, \rho)$  of degree  $m$  over  $\mathbb{C}$ . We know that  $\chi(g) = \sum_{i=1}^m w_i$ , where each  $w_i$  is an  $n$ th root of unity (cf. Proposition 2.1.10). Indeed, the idempotent linear map  $\rho(g)$  is diagonalisable, with matrix  $\text{diag}(w_1, \dots, w_m)$  with respect to an appropriate basis. Hence, we have that  $\rho(g^i) = \text{diag}(w_1^i, \dots, w_m^i)$ , meaning that

$\chi(g^i) = \sum_{j=1}^m w_j^i$ . But this is nothing but  $\sum_{1 \leq i \leq m, (i,n)=1} w^i$ , by assumption. Hence,  $\chi(g)$  is an integer, by Lemma 2.3.7.  $\square$

**Lemma 2.3.9.** Fix  $g \in G$ , and let  $p$  be a prime number. Then,  $\exists! x, y \in G$  such that

1.  $g = xy = yx$
2.  $\text{ord}(x) = p^k$  for some  $k \in \mathbb{N}$
3.  $(\text{ord}(y), p) = 1$

*Proof.* Let  $\text{ord}(g) = up^v$ , where  $(u, v) = 1$ . By Bézout's Lemma, we know that  $\exists a, b \in \mathbb{Z}$  such that  $au + bp^v = 1$ . Then, we can define  $x = g^{au}$  and  $y = g^{bp^v}$ . This satisfies all the conditions:

1.  $g = xy = g^{au} g^{bp^v} = g^{bp^v} g^{au} = yx$ .
2.  $x^{p^v} = 1$ .
3.  $y^v = 1$ .

One can also show  $x$  and  $y$  to be the only elements of  $G$  satisfying these conditions.  $\square$

**Definition 2.3.10** (The  $p$ -  $p'$ -parts of  $g$ ). For any  $g \in G$ , call  $x$  and  $y$  from Lemma 2.3.9 the  $p$ - and  $p'$ -parts of  $g$  respectively.

For the remainder of this subsection, let  $n = |G|$ , and let  $\zeta = e^{\frac{2\pi i}{n}}$  be a primitive  $n$ th root of unity. Define  $\mathbb{Z}[\zeta]$  to be the subring of  $\mathbb{C}$  generated by  $\mathbb{Z}$  and  $\zeta$ . Let  $p$  be a prime number and  $p\mathbb{Z}[\zeta]$  be the principal ideal of  $\mathbb{Z}[\zeta]$  generated by  $p$ . By the Correspondence Theorem, the ideals of  $\mathbb{Z}[\zeta]$  containing  $p\mathbb{Z}[\zeta]$  are in bijection with the ideals of  $\mathbb{Z}[\zeta]/p\mathbb{Z}[\zeta]$ . Since the latter object is finite, it contains finitely many ideals, meaning that only finitely many of the ideals of  $\mathbb{Z}[\zeta]$  contain  $p\mathbb{Z}[\zeta]$ . We can then look at the maximal (proper) ideal amongst these, which is a maximal ideal of  $\mathbb{Z}[\zeta]$ . Denote it by  $P$ . Indeed, we can show that  $P \cap \mathbb{Z} = p\mathbb{Z}$ .

**Theorem 2.3.11.** Let  $g \in G$ , and let  $y$  be the  $p'$ -part of  $g$  for some  $p$  prime. For all characters  $\chi$  of  $G$ ,  $\chi(g) - \chi(y)$  lies in the maximal ideal  $P$ .

*Proof.* Let  $m = \text{ord}(g) = up^\nu$ . Let  $a, b \in \mathbb{Z}$  be such that  $au + bp^\nu = 1$  (as in the proof of Lemma 2.3.9). We have that  $y = g^{bp^\nu}$ . We know that  $\chi(g), \chi(y) \in \mathbb{Z}[\zeta]$ .

Now, let  $w$  be an  $m$ th root of unity. Since  $m|n$  (by Lagrange's Theorem), we know that  $w \in \mathbb{Z}[\zeta]$ . We have that  $w = w^{au+bp^\nu}$ . Raising both sides to the  $p^\nu$ th power, we get that  $w^{p^\nu} = w^{aup^\nu} w^{bp^{2\nu}}$ . Since  $w^{up^\nu} = w^m = 1$ , we have that  $w^{p^\nu} = w^{bp^{2\nu}}$ .

Now, consider the binomial expansion of  $(w - w^{bp^\nu})^{p^\nu}$ . Some blah blah, use fact that  $P$  is a prime ideal (since it is maximal). □

This theorem has several important consequences.

**Corollary 2.3.12.** *Let  $g \in G$  and  $y$  be the  $p'$ -part of  $g$  for some prime  $p$ . Let  $\chi$  be a character of  $G$ .*

1. *If  $\chi(g), \chi(y) \in \mathbb{Z}$ , then  $\chi(g) \equiv \chi(y) \pmod{p}$ .*
2. *If  $\text{ord}(g) = p^k$  for some  $k \in \mathbb{N}$ , then  $\chi(g) \equiv \chi(1) \pmod{p}$ .*

**Lemma 2.3.13.** *Let  $g, h \in G$ . Then,  $g$  is conjugate to  $h$  iff for all characters  $\chi$  of  $G$ ,  $\chi(g) = \chi(h)$ .*

*Proof.*

( $\implies$ ) Seen Before

( $\impliedby$ ) As we know,  $\text{Irr}(G)$  is an orthonormal basis for  $\mathcal{F}_C(G, \mathbb{C})$ . Let  $f$  be the indicator function on  $g^G$ . Then,  $f(g) = 1 \implies f(h) = 1 \implies h \in g^G$ . □

**Corollary 2.3.14.** *Let  $g \in G$ . Then,  $g$  is conjugate to  $g^{-1}$  iff for all characters  $\chi$  of  $G$ ,  $\chi(g) \in \mathbb{R}$ .*

**Example 2.3.15** (Constructing the Character Table of  $G = \text{PSL}(2, 7)$ ). First, note that  $|G| = 168$  and that  $G$  has 6 conjugacy classes. Denote them by  $C_1, \dots, C_6$  with representatives  $g_1, \dots, g_6$ , with  $g_1 = 1$ . It turns out we have exactly 6 irreducible characters of  $G$ .

We begin filling the table as follows.

$C_G(g_i)$	168	8	4	3	7	7
$\text{ord}(g_i)$	1	2	4	3	7	7
$g_i$	$g_1$	$g_2$	$g_3$	$g_4$	$g_5$	$g_6$
$\chi_1$	1	1	1	1	1	1
$\chi_2$						
$\chi_3$						
$\chi_4$						
$\chi_5$						
$\chi_6$						

We can then fill in the first column by applying Corollary 2.2.4.

$C_G(g_i)$	168	8	4	3	7	7
$\text{ord}(g_i)$	1	2	4	3	7	7
$g_i$	$g_1$	$g_2$	$g_3$	$g_4$	$g_5$	$g_6$
$\chi_1$	1	1	1	1	1	1
$\chi_2$	7					
$\chi_3$	8					
$\chi_4$	3					
$\chi_5$	3					
$\chi_6$	6					

Observe that since the orders are unique for the first four columns, they contain all elements of their respective orders. We can then fill in the third column by applying the Column Orthogonality Relation and the first Lemma from today.

$C_G(g_i)$	168	8	4	3	7	7
$\text{ord}(g_i)$	1	2	4	3	7	7
$g_i$	$g_1$	$g_2$	$g_3$	$g_4$	$g_5$	$g_6$
$\chi_1$	1	1	1	1	1	1
$\chi_2$	7		-1			
$\chi_3$	8		0			
$\chi_4$	3		1			
$\chi_5$	3		1			
$\chi_6$	6		0			

We can then fill in the fourth column using the second point of Corollary 2.3.11.

$C_G(g_i)$	168	8	4	3	7	7
$\text{ord}(g_i)$	1	2	4	3	7	7
$g_i$	$g_1$	$g_2$	$g_3$	$g_4$	$g_5$	$g_6$
$\chi_1$	1	1	1	1	1	1
$\chi_2$	7		-1	1		
$\chi_3$	8		0	-1		
$\chi_4$	3		1	0		
$\chi_5$	3		1	0		
$\chi_6$	6		0	0		

We now have four possibilities for the second column.

$C_G(g_i)$	168	8	4	3	7	7
$\text{ord}(g_i)$	1	2	4	3	7	7
$g_i$	$g_1$	$g_2$	$g_3$	$g_4$	$g_5$	$g_6$
$\chi_1$	1	1	1	1	1	1
$\chi_2$	7		-1	1		
$\chi_3$	8		0	-1		
$\chi_4$	3		1	0		
$\chi_5$	3		1	0		
$\chi_6$	6		0	0		

$C_G(g_i)$	168	8	4	3	7	7
$\text{ord}(g_i)$	1	2	4	3	7	7
$g_i$	$g_1$	$g_2$	$g_3$	$g_4$	$g_5$	$g_6$
$\chi_1$	1	1	1	1	1	1
$\chi_2$	7		-1	1		
$\chi_3$	8		0	-1		
$\chi_4$	3		1	0		
$\chi_5$	3		1	0		
$\chi_6$	6		0	0		

For the last two columns of the table, we use row orthogonality, in combination with the fact that  $g_5 = g_6^{-1}$ .

$C_G(g_i)$	168	8	4	3	7	7
$\text{ord}(g_i)$	1	2	4	3	7	7
$g_i$	$g_1$	$g_2$	$g_3$	$g_4$	$g_5$	$g_6$
$\chi_1$	1	1	1	1	1	1
$\chi_2$	7		1	-1	0	0
$\chi_3$	8		-1	0	1	1
$\chi_4$			0	1	$z$	$\bar{z}$
$\chi_5$	3		0	1	$\bar{z}$	$z$
$\chi_6$	6		0	0	$t$	$\bar{t}$

FINAL COMMENTS. Also use the results on  $p$  groups, since  $G$  is a 7-group.

# Chapter 3

## Applications to the Study of Groups

Welcome to the third chapter.

### 3.1 First Examples

#### 3.1.1 A Word on Simple Groups

First, we have an interesting result on  $p$ -groups.

**Lemma 3.1.1.** *Assume that  $|G| = p^n$  for some  $p$  prime and  $n \in \mathbb{N}$ . Then,  $\forall \chi \in \text{Irr}(G)$ ,  $\chi(1)$  is a power of  $p$ .*

*Proof.* Let  $\text{Irr}(G) = \{\chi_1, \dots, \chi_k\}$ , with  $\chi_1$  being the trivial character. sorry

□

**Corollary 3.1.2.** *If  $|G| = p^2$  for some  $p$  prime, then  $\forall \chi \in \text{Irr}(G)$ ,  $\chi(1) = 1$ . In particular,  $G$  is abelian.*

*Proof.* sorry

□

We now have an interesting result on the characters of simple groups.

**Lemma 3.1.3.** *If  $G$  is simple,  $G$  does not admit an irreducible character of degree 2.*

*Proof.* Suppose, for contradiction, that  $G$  is simple but admits an irreducible representation  $\rho : G \rightarrow \text{GL}(2, \mathbb{C})$ . Since  $G$  is simple, we must have that  $\ker(\rho) = \{1\}$ .

If  $G$  is nonabelian, then  $G' = G$ . This tells us that there are no nontrivial characters of degree 1. Since the map  $\rho \mapsto \det(\rho(g))$  a linear character (ie, has degree 1), we can conclude that  $\det(\rho(g)) = 1$  for all  $g \in G$ . By Theorem 2.3.6, we know that  $2 \mid |G|$ . Then, by Cauchy's Theorem,  $\exists g \in G$  such that  $g \neq 1$  but  $g^2 = 1$ . This tells us that  $\rho(g) = -\text{id} \in Z(G)$ , which is absurd, since  $G$  is simple.  $\square$

## 3.2 Burnside's Theorem

### 3.2.1 The Algebraic Numbers

In this subsection, we investigate a generalisation of the algebraic integers, whose properties will be useful in the proof of Burnside's Theorem. We begin with the following definition.

**Definition 3.2.1** (Algebraic Numbers). An algebraic number is a complex number that is a root of a non-zero polynomial in  $\mathbb{Q}[X]$ .

*Remark* (A few recollections on the notion of a minimal polynomial). For any algebraic number  $x$ ,

- There exists a *unique* monic polynomial of minimal degree over  $\mathbb{Q}$  that annihilates  $x$ . This polynomial, denoted  $m_x$ , is called the *minimal polynomial* of  $x$ .
- $m_x$  is irreducible.
- $m_x$  divides any polynomial over  $\mathbb{Q}$  for which  $x$  is a root.

**Definition 3.2.2** (Conjugates of an Algebraic Number). Let  $x$  be an algebraic number. The conjugates of  $x$  are the roots of its minimal polynomial,  $m_x$ .

**Example 3.2.3.** Fix  $n \in \mathbb{N}$ , and let  $\omega$  be an  $n$ th root of unity. The minimal polynomial of  $\omega$  divides  $X^n - 1$ , meaning that all of its roots are also  $n$ th roots of unity, and therefore, have modulus 1.

Indeed, it turns out that if a number is an algebraic integer, then its minimal polynomial actually has integer coefficients.

**Lemma 3.2.4.** *Let  $\alpha, \beta$  be algebraic numbers, and let  $r \in \mathbb{Q}$ . Then,*

1. *The conjugates of  $\alpha + \beta$ <sup>1</sup> are all of the form  $\alpha' + \beta'$ , where  $\alpha'$  and  $\beta'$  are conjugates of  $\alpha$  and  $\beta$  respectively.*
2. *The conjugates of  $r\alpha$ , where  $r \in \mathbb{Q}$ , are all of the form  $r\alpha'$ , where  $\alpha'$  is a conjugate of  $\alpha$ .*

*Proof sketch.* Let  $L$  denote the splitting field over  $\mathbb{Q}$  of  $m_\alpha$ ,  $m_\beta$  and  $m_{\alpha+\beta}$ . This is a normal extension of  $\mathbb{Q}$  [JUSTIFY]. Now, let  $G = \text{Aut}(L/\mathbb{Q})$ . One can show the action of  $G$  on the conjugates of  $\alpha$  to be transitive [JUSTIFY]. For instance, one can show that  $\mathbb{Q}(\alpha) \cong \mathbb{Q}(\alpha')$  [relevance?]. Then, for all  $g \in G$ , we have that  $g(\alpha + \beta) = g(\alpha) + g(\beta)$ , and  $g(x)$  is a conjugate of  $x$  for any  $x \in L$  (by transitivity). I think the transitivity/normality comes from the fact that  $L$  is the splitting field of irreducible polynomials.  $\square$

**Lemma 3.2.5.** *Let  $G$  be a finite group, and let  $\chi$  be a character of  $G$ . Then,  $\left| \frac{\chi(g)}{\chi(1)} \right| \leq 1$ , and if  $0 < \left| \frac{\chi(g)}{\chi(1)} \right| < 1$ , then  $\chi(g)/\chi(1)$  is not an algebraic integer.*

*Proof.* Let  $\gamma = \frac{\chi(g)}{\chi(1)}$  and  $d = \chi(1)$ . Then,  $\chi(g) = w_1 + \cdots + w_d$ , where  $|w_i| = 1$  for all  $i$ . This then gives us that  $|\gamma| \leq 1$ . Now, suppose that  $\gamma$  is an algebraic integer and that  $|\gamma| < 1$ . We show that  $\chi(g) = 0$ .

Let  $m_\gamma$  be the minimal polynomial of  $\gamma$ . Then,  $m_\gamma(X) = X^d + a_{d-1}X^{d-1} + \cdots + a_0$ . Since  $\gamma$  is an algebraic integer, we have that  $a_i \in \mathbb{Z}$  for all  $i$ . By the previous lemma, we know that the conjugates of  $\gamma$  are of the form  $\frac{w'_1 + \cdots + w'_d}{d}$ , where  $w'_i$  are conjugates of  $w_i$ . Since  $|w_i| = 1$ , we have that  $|w'_i| = 1$  for all  $i$ .

Now, let  $z$  be the product of all the conjugates of  $\gamma$ —ie, the product of all the roots of  $m_\gamma$ . Then,  $|z| < 1$ . Indeed,  $z = a_0$ , and hence, in particular,  $z \in \mathbb{Z}$ . Therefore, it must be that  $z = 0$ . Hence, it must be that  $m_\gamma(X) = X$ , as it is irreducible. This gives us that  $\gamma = 0$ , and hence,  $\chi(g) = 0$ .  $\square$

---

<sup>1</sup>It is easy to see that  $\alpha + \beta$  is algebraic.

### 3.2.2 The Three Versions of Burnside's Theorem

**Theorem 3.2.6** (Burnside's Theorem for Simple Groups). *Let  $p$  be a prime number, and let  $r \in \mathbb{Z}$  be greater than or equal to 1. Let  $G$  be a finite group which a conjugacy class of size  $p^r$ . Then,  $G$  is not simple.*

*Proof.* Let  $g \in G$  be such that  $|g^G| = p^r$ . Note that since  $G$  contains a conjugacy class of size greater than 1,  $G$  cannot be abelian. Now, let  $\text{Irr}(G) = \{\chi_1, \dots, \chi_k\}$ . The idea is to apply column orthogonality between the  $g$ -column and the 1-column of  $G$ .

By Proposition 2.2.2, we have that

$$\begin{aligned} 0 &= \frac{1}{|G|} \sum_{i=1}^k \chi_i(g) \chi_i(1) \\ &= 1 + \frac{1}{|G|} \sum_{i=2}^k \chi_i(g) \chi_i(1) \end{aligned}$$

Dividing both sides by  $p$ , we get that

$$\sum_{i=2}^k \chi_i(g) \frac{\chi_i(1)}{p} = -\frac{1}{p}$$

Since  $-1/p$  is not an algebraic integer, this implies that for some  $2 \leq j \leq k$ ,  $\chi_j(g) \frac{\chi_j(1)}{p}$  is not an algebraic integer. However, since  $\chi_j(g)$  is necessarily an algebraic integer, it must be that  $\chi_j(1)/p$  is not an algebraic integer. Since  $\chi_j(1) \in \mathbb{Z}$  (as it is the degree of the associated representation) and  $p$  is prime, this is equivalent to saying that  $p \nmid \chi_j(1)$ . Since  $|g^G| = p^r$ , this means that  $\chi_j(1)$  and  $|g^G|$  are coprime.

We know, by Bézout's Lemma, that there exist integers  $a, b$  such that  $a|g^G| + b\chi_j(1) = 1$ . Multiplying by the character ratio  $\gamma = \chi_j(g)/\chi_j(1)$ , we have that

$$a|g^G|\gamma + b\chi_j(g) = \gamma$$

By Lemma 2.3.3 (make reference more precise), we know that  $a|g^G|\gamma$  is an algebraic integer. This means that  $\gamma$  must be an algebraic integer too, giving us that  $|\gamma| = 1$  (by Lemma 3.2.5).

Now, let  $\rho$  be the representation with character  $\chi_j$ . Then, by Lemma 2.3.3, we have that  $\rho(g) = \lambda I$ , where  $\lambda = |g^G| \gamma$ . Finish using picture on iPad.  $\square$

**Theorem 3.2.7** (Burnside's Theorem for Groups of Order  $p^a q^b$ ). *Let  $G$  be a finite group of order  $p^a q^b$ , where  $p, q$  are prime numbers and  $a, b \in \mathbb{N}$ . Then,  $G$  is simple only if  $|G| \in \{p, q\}$ .*

*Proof.* First, suppose that  $b = 0$ . Then,  $G$  is a  $p$ -group, and hence, has a nontrivial centre.<sup>2</sup> This means that  $G$  is not simple unless  $|G| = p$ . One can prove similarly that if  $a = 0$  then  $|G| = q$ .

Now, suppose that  $a, b > 0$ . Then,  $G$  has a normal Sylow  $p$ -subgroup  $P$  of order  $p^a$  for some  $a \in \mathbb{N}$ . Since  $P$  is a  $p$ -group, its centre is nontrivial, and therefore, there exists some  $g \in Z(P) \setminus \{1\}$ . Indeed,

$$\begin{aligned} P &\leq C_G(g) \\ \implies |P| \mid |C_G(g)| &= \frac{|G|}{|g^G|} \\ \implies p^a |g^G| \mid p^a q^b \\ \implies |g^G| \mid q^b \end{aligned}$$

where we justify the first inclusion by writing it out [DO IT!].

Since  $G$  is simple,  $Z(G) = \{1\}$ , meaning that  $|g^G| = q^r$  for some  $r \geq 1$ . This contradicts the simplicity of  $G$ . [JUSTIFY!]  $\square$

Insert definition of solvable

**Theorem 3.2.8** (Burnside's Theorem for Solvable Groups). *Let  $G$  be a finite group. If  $G$  has order  $p^a q^b$ , where  $p, q$  are prime and  $a, b \geq 0$ , then  $G$  is solvable.*

*Proof.* We argue by induction on  $|G|$ . If  $|G| = 1$ , then  $G$  is trivially solvable. Now, suppose that

---

<sup>2</sup>Recall that the sizes of the conjugacy classes of a  $p$ -group are prime powers. One can then use the Class Equation to arrive at this result.

$|G| = p^a q^b$ , where  $a, b \geq 0$ . If  $a = 0$  or  $b = 0$ , then  $G$  is a  $p$ -group or a  $q$ -group, and hence, solvable.<sup>3</sup> Else, if  $a, b \geq 1$ , then by Theorem 3.2.7, we know that  $G$  is not simple. It then contains a nontrivial normal subgroup  $N$ . By the Induction Hypothesis, both  $N$  and  $G/N$  are solvable, making  $G$  solvable as well.  $\square$

### 3.2.3 Applications of Burnside's Theorem

**Lemma 3.2.9.** *There are no nonabelian simple groups of order less than 30.*

## 3.3 Products, Products, Products

Thus far, we have seen two ways of combining representations of a group  $G$ : the direct sum and the tensor product. While we have investigated the properties of the former in detail, we have yet to explore the latter. This will be the primary focus of this section, which we have included in this chapter because we will explore the properties of tensor products of representations by relating them to those of direct products of groups. In particular, our investigation of tensor products will be from a primarily application-driven perspective.

### 3.3.1 The Multiplicative Properties of (Irreducible) Characters

We begin by inviting the reader to refresh their memory on what we have seen so far by taking a look at Subsection 1.2.5 and the seventh point of Proposition 2.1.10. Before we proceed any further, we establish certain results about the multiplicative properties of characters, with the multiplication in question being that induced by the standard multiplicative structure of  $\mathcal{F}_C(G, \mathbb{C})$  (which, in turn, inherits its multiplication from  $\mathbb{C}$ ).

**Lemma 3.3.1.** *The set  $R(G) := \mathbb{Z}\text{Irr}(G) \subseteq \mathcal{F}_C(G, \mathbb{C})$  is a subring of  $\mathcal{F}_C(G, \mathbb{C})$ .*

*Proof.* Observe that  $R(G)$  is certainly a group under addition. We claim that it is closed under multiplication, with multiplicative identity given by the trivial character.

Let  $\chi_V, \chi_W \in \text{Irr}(G)$ , with associated (simple)  $\mathbb{C}G$ -modules  $V$  and  $W$ . From Proposition 2.1.10,

---

<sup>3</sup>Give/link a proof of this!

we know that their product  $\chi_V \chi_W$  is the character associated to the  $\mathbb{C}G$ -module  $V \otimes W$ .  $\square$

**Corollary 3.3.2.** *The set  $L(G) := \{\chi \in \text{Irr}(G) : \chi(1) = 1\}$  of degree 1 characters is a multiplicative subgroup of  $R(G)$ .*

*Proof.* Obviously, the trivial character is linear, making  $L(G)$  nonempty. Further, for all  $\chi_V, \chi_W \in L(G)$  (with associated  $\mathbb{C}G$ -modules  $V$  and  $W$ ), clearly,  $\chi_V \chi_W$  is a character (namely, that of  $V \otimes W$ ), and  $(\chi_V \chi_W)(1) = 1$ , proving closure under multiplication. Finally, the inverse of any character  $\chi_V$  (with associated  $\mathbb{C}G$ -module  $V$ ) is given by the character  $\chi_{V^*}$  of its dual  $\mathbb{C}G$ -module  $V^*$ , which is also linear, proving the desired result.  $\square$

**Lemma 3.3.3.** *Let  $\chi_V, \chi_W \in \text{Irr}(G)$ , with  $\chi_V(1) = 1$ . Then,  $\chi_V \chi_W \in \text{Irr}(G)$ .*

*Proof.* Recall, from Proposition 2.1.16, that  $\chi_V \chi_W$  is irreducible iff  $\langle \chi_V \chi_W, \chi_V \chi_W \rangle = 1$ . Indeed, we have that

$$\begin{aligned} \langle \chi_V \chi_W, \chi_V \chi_W \rangle &= \frac{1}{|G|} \sum_{g \in G} \chi_V(g) \cdot \chi_W(g) \cdot \overline{\chi_V(g) \cdot \chi_W(g)} \\ &= \frac{1}{|G|} \sum_{g \in G} \chi_V(g) \cdot \chi_W(g) \cdot \overline{\chi_V(g)} \cdot \overline{\chi_W(g)} \\ &= \frac{1}{|G|} \sum_{g \in G} \chi_W(g) \cdot \overline{\chi_W(g)} = 1 \end{aligned}$$

We justify the second equality by seeing that  $\chi_V(g) \cdot \overline{\chi_V(g)} = 1$  because  $\overline{\chi_V(g)} = \chi_V(g^{-1})$ . Indeed, since  $\chi_V$  is of degree 1, it is, in fact, *equal* to its underlying representation, making it multiplicative (ie,  $\chi_V(g) \cdot \chi_V(g^{-1}) = \chi_V(gg^{-1}) = 1$ ). The last equality follows from the fact that  $\chi_W \in \text{Irr}(G)$ .  $\square$

### 3.3.2 Tensor Products and Direct Products

**Definition 3.3.4** (Tensor Products of Modules of Different Groups). Let  $K$  be a field, and let  $G$  and  $H$  be finite groups. Let  $V$  be a  $KG$ -module and let  $W$  be a  $KH$ -module. The tensor product  $V \otimes_K W$  of  $V$  and  $W$  over  $K$  is the  $K(G \times H)$ -module with scalar

multiplication

$$(g, h) \cdot (v \otimes w) = (g \cdot v) \otimes (h \cdot w) \quad (3.3.1)$$

for all  $g \in G$ ,  $h \in H$ ,  $v \in V$ , and  $w \in W$ .

**Proposition 3.3.5.** *Let  $G, H$  be finite groups and let  $V$  be a  $\mathbb{C}G$ -module and  $W$  a  $\mathbb{C}H$ -module. Then, the character  $\chi_{V \otimes W}$  associated to the  $\mathbb{C}(G \times H)$ -module  $V \otimes W$  is given by*

$$\chi_{V \otimes W}(g, h) = \chi_V(g) \chi_W(h)$$

for all  $g \in G$  and  $h \in H$ .

*Proof.* We essentially consider  $V$  and  $W$  as  $\mathbb{C}(G \times H)$ -modules and then apply the definition of the tensor product. Finish!  $\square$

**Notation.** Let  $G, H$  be finite groups and let  $V$  be a  $\mathbb{C}G$ -module and  $W$  a  $\mathbb{C}H$ -module. Then, the character of the tensor product  $V \otimes W$  is denoted  $\chi_V \times \chi_W$ .

**Theorem 3.3.6.**  $\text{Irr}(G \times H) = \{\chi \times \psi : \chi \in \text{Irr}(G), \psi \in \text{Irr}(H)\}$ .

*Proof.* Let  $\text{Irr}(G) = \{\chi_1, \dots, \chi_k\}$  and let  $\text{Irr}(H) = \{\psi_1, \dots, \psi_r\}$ . The conjugacy classes of  $G \times H$  are of the form  $g^G \times h^H$  for  $g \in G$  and  $h \in H$  (exercise). We show that  $\chi_i \times \psi_j$  is irreducible for all  $1 \leq i \leq k, 1 \leq j \leq r$ , with the characters being distinct (ie, if  $i \neq \ell$  or  $j \neq m$  then  $\chi_i \times \psi_j \neq \chi_\ell \times \psi_m$ ).

We use the fact that a character is irreducible iff its character is 1 (insert reference). Indeed, for all  $1 \leq i, \ell \leq k$  and  $1 \leq j, m \leq r$ ,

$$\begin{aligned} \langle \chi_i \times \psi_j, \chi_\ell \rangle &= \frac{1}{|G \times H|} \sum_{(g, h) \in G \times H} \chi_i(g) \psi_j(h) \chi_\ell(g^{-1}) \psi_m(h^{-1}) \\ &= \left( \frac{1}{|G \times H|} \sum_{g \in G} \chi_i(g) \chi_\ell(g^{-1}) \right) \left( \sum_{h \in H} \psi_j(h) \psi_m(h^{-1}) \right) \\ &= \delta_{i\ell} \delta_{jm} \end{aligned}$$

Fill in missing computations---it's not hard. □

**Example 3.3.7** (The Acyclic Group of Order 9). Let  $G = H = C_3 = \langle g \rangle$ , the cyclic group of order 3 generated by  $g$ , acting irreducibly on  $V = W = \mathbb{R}^2$  via

$$g \cdot \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} -y \\ xy \end{bmatrix}$$

In other words, let its associated representation  $\rho : G \rightarrow \text{GL}(2, \mathbb{R})$  be given by the matrix

$$\rho(g) = \begin{bmatrix} 0 & -1 \\ 1 & -1 \end{bmatrix}$$

with respect to the standard basis.

It is useful to think about powers of characters.

**Notation.** Let  $G$  be a finite group and let  $\chi$  be a character of  $G$ . Then, for all  $n \in \mathbb{N}$ , the  $n$ th power of  $\chi$  is the character  $\chi^n$  of  $G$  given by

$$\chi^n = \underbrace{\chi \times \cdots \times \chi}_{n \text{ times}}$$

**Theorem 3.3.8.** Let  $G$  be a finite group and let  $\chi$  be a faithful character of  $G$ . Suppose that  $|\{\chi(g) : g \in G\}| = r$ . For all  $\psi \in \text{Irr}(G)$ ,  $\exists 0 \leq i \leq r-1$  such that  $\langle \psi, \chi^i \rangle \neq 0$ .

*Proof.* Let  $G = \{g_1 = 1, g_2, \dots, g_r\}$ . FINISH! □

## 3.4 The Character Theory of Subgroups

In this section, we will explore how we can understand the characters of a group using those of its subgroups and vice-versa. We will begin by discussing the latter, which we will study from the perspective of Restriction. We will then discuss the former, which we will study from the perspective of Induction.

### 3.4.1 Restriction

For the entirety of this subsection, let  $G$  be a finite group and let  $H \leq G$ .

**Definition 3.4.1** (Restriction of a Representation). Let  $(V, \rho)$  be a complex representation of  $G$  with associated character  $\chi$ . The restriction of  $(V, \rho)$  to  $H$ , denoted  $V \downarrow H$ ,  $\text{Res}_H^G(V)$  or  $V_H$ , is the set representation  $(V, \rho|_H)$ . We will denote its associated character  $\chi \downarrow H$  or  $\chi_H$ .

**Notation.** To distinguish between inner-products of central functions considered over  $H$  and those over  $G$ , we will denote the former by  $\langle \cdot, \cdot \rangle_H$ . In similar fashion to (2.1.1), we have, for all  $\psi_1, \psi_2 \in \mathcal{F}_C(H, \mathbb{C})$ ,

$$\langle \psi_1, \psi_2 \rangle_H := \frac{1}{|H|} \sum_{h \in H} \psi_1(h) \overline{\psi_2(h)} \quad (3.4.1)$$

**Proposition 3.4.2.** Fix  $\psi \in \text{Irr}(H)$ . Then, there exists an irreducible character  $\chi$  of  $G$  such that the inner-product  $\langle \chi \downarrow H, \psi \rangle_H$  is nonzero.

*Proof.* Let  $\text{Irr}(G) = \{\chi_1, \dots, \chi_k\}$ . Consider the regular character  $\chi_{\text{reg}}$  of  $G$ . We then have (insert reference) that for all  $g \in G$ ,

$$\chi_{\text{reg}} = \sum_{i=1}^k \chi_i(1) \chi_i = \begin{cases} |G| & \text{if } g = 1 \\ 0 & \text{otherwise} \end{cases}$$

We now show that  $\langle \chi_{\text{reg}} \downarrow H, \psi \rangle_H$  is nonzero:

$$\begin{aligned} \langle \chi_{\text{reg}} \downarrow H, \psi \rangle_H &= \frac{1}{|H|} \sum_{h \in H} \chi_{\text{reg}}(h) \overline{\psi(h)} \\ &= \frac{1}{|H|} |G| \overline{\psi(1)} \neq 0 \end{aligned}$$

Considering the decomposition of  $\chi_{\text{reg}}$  as a sum of irreducible characters, we see that one of the summands must have a nonzero inner-product with  $\psi$ . □

*Remark.* In general, we can compute  $\text{Irr}(H)$  from  $\text{Irr}(G)$  quite easily if  $[G : H]$  is small. However, if  $[G : H]$  is large, then this can get difficult.

**Proposition 3.4.3.** Fix  $\chi \in \text{Irr}(G)$ , and write  $\text{Irr}(H) = \{\psi_1, \dots, \psi_r\}$ . Then,  $\exists d_1, \dots, d_r \in \mathbb{N}$  such that

$$\chi \downarrow H = \sum_{i=1}^r d_i \psi_i \quad \text{and} \quad \sum_{i=1}^r d_i^2 \leq [G : H]$$

Moreover, the above inequality is an equality if and only if  $\forall g \in G \setminus H$ , we have  $\chi(g) = 0$ .

*Proof.* It is clear that  $\exists d_1, \dots, d_r$  such that  $\chi \downarrow H = \sum_{i=1}^r d_i \psi_i$ . To arrive at the inequality, we consider the inner-product of  $\chi \downarrow H$  with itself:

$$\begin{aligned} \langle \chi \downarrow H, \chi \downarrow H \rangle_H &= \frac{1}{|H|} \sum_{h \in H} \chi(h) \overline{\chi(h)} \\ &= \frac{[G : H]}{|G|} \sum_{h \in H} \chi(h) \overline{\chi(h)} \end{aligned}$$

Now, since  $\chi$  is irreducible (over  $G$ ), we have that

$$\begin{aligned} 1 = \langle \chi, \chi \rangle &= \frac{1}{|G|} \sum_{g \in G} \chi(g) \overline{\chi(g)} \\ &= \frac{1}{|H|} \sum_{g \in H} \chi(g) \overline{\chi(g)} + \underbrace{\frac{1}{|G|} \sum_{g \in G \setminus H} \chi(g) \overline{\chi(g)}}_{=: K} \end{aligned}$$

We then have that

$$[G : H] = \sum_{i=1}^r d_i^2 + [G : H] K$$

Clearly, this quantity is greater than or equal to  $\sum_{i=1}^r d_i^2$ . Furthermore,  $[G : H] K = 0$  iff  $K = 0$ , which is true iff  $\chi(g) = 0$  for all  $g \in G \setminus H$ .  $\square$

**Proposition 3.4.4.** Assume  $H$  is a normal subgroup of  $G$ . Let  $V$  be a simple  $\mathbb{C}G$ -module. Then, all simple constituents<sup>4</sup> of its restriction to  $H$  have the same dimension.

*Proof.* Let  $U \leq V$  be a simple  $\mathbb{C}H$ -submodule of  $V$ . Since  $H$  is normal, for all  $g \in G$ , the set  $gU$  is also a  $\mathbb{C}H$ -submodule of  $V$ : indeed, for all  $h \in H$ ,  $hgU = gh'U = gU$  where  $h' = g^{-1}hg$ .

<sup>4</sup>ie, summands in its direct sum decomposition into simple modules

Now, let  $W := \sum_{g \in G} gU$ . Since  $W$  is a nonzero  $\mathbb{C}G$ -submodule of  $V$ , and since  $V$  is simple, we have that  $W = V$ . Indeed, since  $U$  is simple, so is  $gU$  for every  $g \in G$ . This tells us that for all  $g_1, g_2 \in G$ ,

$$g_1U \cap g_2U = \begin{cases} 0 & \text{in some cases} \\ g_1U & \text{otherwise} \end{cases}$$

as  $g_1U \cap g_2U$  is a submodule of the (simple) module  $g_1U$ .<sup>5</sup>

Hence, the sum in the definition of  $W$ , considered only over indices  $i$  such that distinct summands have zero intersection, is direct. Therefore, all FINISH!  $\square$

**Corollary 3.4.5.** *Assume  $H$  is a normal subgroup of  $G$ . Fix  $\chi \in \text{Irr}(G)$ . Then, all irreducible constituents of  $\chi \downarrow H$  have the same degree.*

**Proposition 3.4.6.** *Let  $H$  be normal in  $G$ , of degree 2. Fix  $\chi \in \text{Irr}(G)$ . Then,  $\chi \downarrow H$  is either irreducible or the sum of two irreducible characters of equal degree.*

*Proof.* Let  $\text{Irr}(H) = \{\phi_1, \dots, \phi_r\}$ . By Proposition 3.4.3, we have that  $\chi \downarrow H = \sum_{i=1}^r d_i \phi_i$  for some  $d_1, \dots, d_r \in \mathbb{N}$ . Since  $[G : H] = 2$ , we have that  $\sum_{i=1}^r d_i^2 \leq 2$ . This implies that either  $r = 1$  or  $r = 2$  and  $d_1 = d_2 = 1$ . Refine a bit  $\square$

*Remark.* Consider the situation described in the above proposition. We have that  $G/H \cong C_2$ , the cyclic group of order 2. By the Representation Theory of Cyclic Groups (cf. add reference), we have that there is a linear character  $\lambda$  of  $G/H$  such that for all  $gH \in G/H$ ,

$$\lambda(gH) = \begin{cases} -1 & \text{if } g \notin H \\ 1 & \text{if } g \in H \end{cases}$$

This lifts to a character  $\bar{\lambda}$  of  $G$  given by  $\bar{\lambda}(g) = \lambda(gH)$ . We then have that for all  $\chi \in \text{Irr}(G)$ ,  $\bar{\lambda}\chi$  is irreducible, agreeing with  $\chi$  upon restriction to  $H$ .

**Lemma 3.4.7.** *either  $\chi$  or  $\bar{\lambda}\chi$*

---

<sup>5</sup>According to Dr. Rizzoli, "there is no naïve answer" to the question of when the intersection is zero and when it is not.

*Proof.* We have that for all  $g \in G$ ,

$$(\chi + \bar{\chi})(g) = \begin{cases} 0 & \text{if } g \notin H \\ 2\chi(g) & \text{if } g \in H \end{cases}$$

Now, let  $\chi_2$  be an irreducible character of  $G$  such that  $\chi_2 \downarrow H = \chi \downarrow H$ . We show that  $\chi_2$  is either  $\chi$  or  $\bar{\chi}$ . To that end, we compute the inner-product of  $\chi + \bar{\chi}$  with  $\chi_2$ :

$$\begin{aligned} \langle \chi + \bar{\chi}, \chi_2 \rangle &= \frac{1}{|G|} \sum_{g \in G} (\chi(g) + \bar{\chi}(g)) \overline{\chi_2(g)} \\ &= \frac{1}{|G|} \sum_{g \in H} 2\chi(g) \overline{\chi_2(g)} \\ &= \frac{1}{|H|} \sum_{g \in H} \chi(g) \overline{\chi_2(g)} \\ &= \langle \chi \downarrow H, \chi \downarrow H \rangle_H = 1 \end{aligned}$$

□

**Proposition 3.4.8.** *Let  $H$  have index 2 in  $G$ . Let  $\chi \in \text{Irr}(G)$  be expressible as  $\psi_1 + \psi_2$ , for  $\psi_1, \psi_2 \in \text{Irr}(H)$ . Let  $\phi \in \text{Irr}(G)$  be such that  $\langle \phi \downarrow H, \psi_i \rangle_H \neq 0$  for  $i = 1$  or  $i = 2$ . Then,  $\phi = \chi$ .*

*Proof.* Since  $[G : H] = 1 + 1$ , by Proposition 3.4.3, we have that  $\chi(g) = 0$  for all  $g \in G \setminus H$ . Computing the inner-product, we get that

$$\begin{aligned} \langle \phi, \chi \rangle &= \frac{1}{|G|} \sum_{g \in G} \phi(g) \overline{\chi(g)} \\ &= \frac{1}{|H|} \sum_{h \in H} \phi(h) \overline{\chi(h)} \\ &= \frac{1}{2} \langle \phi \downarrow H, \chi \rangle_H \neq 0 \end{aligned}$$

proving that  $\phi = \chi$ . Need more details!

□

### 3.4.2 Induction

In this subsection, we will describe a process whereby we can use the representation theory of the subgroups of  $G$  to understand that of  $G$ . For the remainder of this section, let  $H$  be a subgroup of  $G$ .

The situation we will attempt to understand is the following. Given  $U$  a  $\mathbb{C}H$ -submodule of  $\mathbb{C}H$  (which in turn is a submodule of  $\mathbb{C}G$ ), we will attempt to understand the  $\mathbb{C}G$ -submodule of  $GU$ , which we will refer to as the *induced module* of  $U$ . We will define this more formally very soon.

First, observe that the  $\mathbb{C}G$ -module  $\mathbb{C}G$  is naturally a right  $\mathbb{C}H$ -module with action  $h(g) = gh$ . Hence, taking the tensor product of  $\mathbb{C}G$  with a  $\mathbb{C}H$ -module over  $\mathbb{C}H$  is a sensible thing to do.

**Definition 3.4.9** (Induced Module). Let  $V$  be a  $\mathbb{C}H$ -module. The induced module of  $V$  from  $H$  to  $G$ , denoted  $\text{Ind}_H^G(V)$ ,  $V^G$  or  $V \uparrow G$ , is the  $\mathbb{C}G$ -module  $\mathbb{C}G \otimes_{\mathbb{C}H} V$  equipped with scalar multiplication

$$g \cdot (x \otimes v) = gx \otimes v \quad (3.4.2)$$

for all  $g \in G$ ,  $x \in \mathbb{C}G$  and  $v \in V$ .

We can give a more concrete description of the induced module.

**Proposition 3.4.10.** Let  $k = [G : H]$  and let  $g_1, \dots, g_k$  be a complete set of coset representatives (so that  $G = \bigsqcup_{i=1}^k g_i H$ ). As a vector space, we have that

$$\text{Ind}_H^G(V) = \bigoplus_{i=1}^k g_i \otimes V \quad (3.4.3)$$

where we denote by  $g_i \otimes V$  the set of elements of the form  $g_i \otimes v$  for  $v \in V$ .<sup>6</sup> Furthermore,  $\mathbb{C}G$  transitively permutes the summands  $g_i \otimes V$  in (3.4.3) via the action

$$g \cdot (g_i \otimes v) = g_j \otimes v$$

where  $g \in G$  is arbitrary and  $j$  is such that  $gg_i \in g_j H$ .

*Proof.* As a right  $\mathbb{C}H$ -module, we have that

$$\mathbb{C}G = \mathbb{C} \left( \bigsqcup_{i=1}^k g_i H \right)$$

<sup>6</sup>Such a vector space is naturally isomorphic to  $V$ .

$$\begin{aligned}
&= \bigoplus_{i=1}^k \mathbb{C}(g_i H) \\
&= \bigoplus_{i=1}^k g_i \otimes \mathbb{C}H
\end{aligned}$$

Since  $\text{Ind}_H^G(V) = \mathbb{C}G \otimes_{\mathbb{C}H} V$ , replacing  $\mathbb{C}G$  with the above sum, we get that

$$\begin{aligned}
\text{Ind}_H^G(V) &= \left( \bigoplus_{i=1}^k g_i \otimes \mathbb{C}H \right) \otimes_{\mathbb{C}H} V \\
&= \bigoplus_{i=1}^k g_i \otimes (\mathbb{C}H \otimes_{\mathbb{C}H} V) \\
&\cong \bigoplus_{i=1}^k g_i \otimes V
\end{aligned}$$

as in (3.4.3), proving the first part of the proposition.

For the second part, fix  $g \in G$  and  $1 \leq i \leq k$ . Let  $1 \leq j \leq k$  and  $h \in H$  be such that  $gg_i = g_j h$ .

We then have that

$$g(g_i \otimes V) = gg_i \otimes V = g_j h \otimes V = g_j \otimes hV = g_j \otimes V$$

demonstrating that we have the desired permutations of the summands in (3.4.3). The only thing left to show is that this action is transitive. ASK PROF TO CLARIFY TRANSITIVITY □

**Corollary 3.4.11.** *As a  $\mathbb{C}$ -vector space, we have that  $\dim(\text{Ind}_H^G(V)) = [G : H] \cdot \dim(V)$ .*

**Example 3.4.12.** The induced module of the trivial module  $\mathbb{C}$  from  $H$  to  $G$  is the permutation module of  $G$  acting on  $G/H$  by  $g \cdot g_i H = g_j H$ .

We now turn our attention to the characters of the induced module. We will begin by characterising the character of the induced module.

**Proposition 3.4.13.** *If  $V$  is a  $\mathbb{C}H$ -module with character  $\chi$ , the character of the induced module, denoted  $\text{Ind}_H^G(\chi)$ , is given by*

$$\text{Ind}_H^G(\chi)(g) = \frac{1}{|H|} \sum_{x^{-1}gx \in H} \chi(x^{-1}gx)$$

for all  $g \in G$ .

*Proof.* Fix  $g \in G$ . We determine the trace of the action of  $g$  on  $\text{Ind}_H^G(V)$  as follows.

Consider the decomposition  $\text{Ind}_H^G(V) = \bigoplus_{i=1}^k g_i \otimes V$  (as given by (3.4.3), with  $\{g_i\}_{i=1}^k$  being a set of representatives for the elements of  $G/H$ ). Consider the action of  $g$  with respect to a basis given by the various bases of  $g_i \otimes V$ .

DRAW MATRIX FROM iPad

If  $g$  does not fix  $g_i \otimes V$ , then the contribution  $g_i \otimes V$  to  $\text{Tr}(g)$  is zero. If  $g$  does fix  $g_i \otimes V$  (or, equivalently, if  $g_i^{-1}gg_i \in H$ ), then the contribution is given by

$$\chi(g_i^{-1}gg_i) = g(g_i \otimes v) = g_i(g_i g g_i^{-1}) \otimes v = g_i \otimes (g_i g g_i^{-1})v$$

for all  $v \in V$ . We can then conclude that

$$\text{Ind}_H^G(\chi)(g) = \sum_{g_i^{-1}gg_i \in H} \chi(g_i^{-1}gg_i)$$

Indeed, this sum can be extended to a sum over all  $x \in G$  such that  $x^{-1}gx \in H$  (except we need to divide by  $|H|$  when we do so), giving us the desired result. Eh???

□

**Example 3.4.14.** Let  $G = S_3$  and  $H = \{1, (123), (132)\}$ . Choose 1 and (12) as a set of coset representatives for  $G/H$ . Let  $\chi$  be the character of the trivial module of  $H$ . Then,

### 3.4.3 The Relationship between Induction and Restriction

It is no coincidence that we investigated these phenomena in succession. As we shall see, they share an interesting relationship. This turns out to be a consequence of the following important **universal property**.

**Proposition 3.4.15** (The Universal Property of the Induced Module). *Let  $V$  be a  $\mathbb{C}H$ -module. For all  $\mathbb{C}G$ -modules  $W$  and all  $\mathbb{C}H$ -module homomorphisms  $f : V \rightarrow W \downarrow H$ , there exists a unique  $\mathbb{C}G$ -module homomorphism  $\tilde{f} : \text{Ind}_H^G(V) \rightarrow W$  such that the following*

diagram commutes:

$$\begin{array}{ccc}
 V & \xrightarrow{f} & W \downarrow H \\
 \downarrow \iota & & \downarrow \iota' \\
 \text{Ind}_H^G(V) & \xrightarrow{\exists! \tilde{f}} & W
 \end{array} \tag{3.4.4}$$

where  $\iota : V \rightarrow \text{Ind}_H^G(V)$  is the map  $v \mapsto 1 \otimes v$  and  $\iota' : W \downarrow H \rightarrow W$  is the map sorry.

*Proof.* Since  $f$  is a morphism of  $\mathbb{C}H$ -modules, the map  $\bar{f} : \mathbb{C}G \times V \rightarrow W : (x, v) \mapsto xf(v)$  is  $\mathbb{C}H$ -stable: for all  $x, x' \in \mathbb{C}G$ ,  $v, v' \in V$  and  $y \in \mathbb{C}H$ ,

$$\bar{f}(x + x', v) = (x + x')f(v) = xf(v) + x'f(v) = \bar{f}(x, v) + \bar{f}(x', v)$$

$$\bar{f}(x, v + v') = xf(v + v') = xf(v) + xf(v') = \bar{f}(x, v) + \bar{f}(x, v')$$

$$\bar{f}(xy, v) = (xy)f(v) = xyf(v) = xf(yv) = \bar{f}(x, yv)$$

By the Universal Property of the Tensor Product,  $\exists! \tilde{f} : \mathbb{C}G \otimes_{\mathbb{C}H} V \rightarrow W : x \otimes v \mapsto xf(v)$ . It is clear that  $\tilde{f}$  is a morphism of  $\mathbb{C}G$ -modules (is it?). Finally, one can check that the diagram commutes.  $\square$

This gives us the following important relationship between induction and restriction.

**Corollary 3.4.16.** *Let  $V$  be a  $\mathbb{C}H$ -module and  $W$  a  $\mathbb{C}H$ -module, as above. Then, there is an isomorphism of  $\mathbb{C}$ -vector spaces between  $\text{Hom}_{\mathbb{C}H}(V, W \downarrow H)$  and  $\text{Hom}_{\mathbb{C}G}(\text{Ind}_H^G(V), W)$ .*

*Proof.* Fix  $\varphi \in \text{Hom}_{\mathbb{C}G}(\text{Ind}_H^G(V), W)$ . Then,  $\varphi \circ \iota$  is a morphism of  $\mathbb{C}H$ -modules from  $V$  to  $W \downarrow H$ . One can use the Universal Property to show that  $\phi \mapsto \phi \circ \iota$  is  $\mathbb{C}$ -linear, injective and surjective.  $\square$

**Lemma 3.4.17.** *Let  $W_1$  and  $W_2$  be  $\mathbb{C}G$ -modules and with respective characters  $\chi_1$  and  $\chi_2$ . Then,*

$$\dim(\text{Hom}_{\mathbb{C}G}(W_1, W_2)) = \langle \chi_1, \chi_2 \rangle$$

where we consider the dimension to be that of a  $\mathbb{C}$ -vector space.

*Proof.* Exercise in PS 10. TODO: place elsewhere!  $\square$

**Theorem 3.4.18** (Frobenius Reciprocity). *Let  $V$  be a  $\mathbb{C}H$ -module and  $W$  a  $\mathbb{C}G$ -module, with characters  $\chi_V$  and  $\chi_W$  respectively. Then,*

$$\langle \text{Ind}_H^G(\chi_V), \chi_W \rangle_G = \langle V, \text{Res}_H^G(W) \rangle_H$$

*Proof.* This is a direct consequence of the previous lemma and the corollary (reference):

$$\begin{aligned} \langle \text{Ind}_H^G(\chi_V), \chi_W \rangle_G &= \dim(\text{Hom}_{\mathbb{C}G}(\text{Ind}_H^G(V), W)) \\ &= \dim(\text{Hom}_{\mathbb{C}H}(V, W \downarrow H)) \\ &= \langle V, W \downarrow H \rangle_H = \langle V, \text{Res}_H^G(W) \rangle_H \end{aligned}$$

□

**Example 3.4.19** (The Quaternion Group). Let  $G = Q_8$ , the quaternion group of order 8, viewed as a subgroup of  $\text{GL}(2, \mathbb{C})$ . We know it is generated by

$$a = \begin{bmatrix} i & 0 \\ 0 & -i \end{bmatrix} \quad \text{and} \quad b = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}$$

Let  $H = \langle A \rangle \cong C_4$ , the cyclic group of order 4. For  $\chi \in \text{Irr}(H)$ , we determine  $\text{Ind}_H^G(\chi)$ .

Consider the following character table for  $G$ :

	1	-1	$a$	$b$	$ab$
$\chi_1$	1	1	1	1	1
$\chi_2$	1	1	1	-1	-1
$\chi_3$	1	1	1	1	-1
$\chi_4$	1	1	1	-1	1
$\chi_5$	2	-2	-2	0	0

The group  $H$  has 4 irreducible characters, which we denote  $\eta_1, \eta_2, \eta_3, \eta_4$ . Indeed,  $\eta_1 = \chi_1 \downarrow H$  and  $\eta_2 = \chi_3 \downarrow H = \chi_4 \downarrow H$ . Furthermore, Frobenius Reciprocity tells us that  $\chi_1$  and  $\chi_2$  are both constituents of  $\text{Ind}_H^G(\eta_1)$ —indeed, they are the only ones. Similarly,  $\chi_3$  and  $\chi_4$  are both constituents of  $\text{Ind}_H^G(\eta_2)$ . Finally, no linear character is a constituent of  $\text{Ind}_H^G(\eta_3)$  or  $\text{Ind}_H^G(\eta_4)$ .
